Example: Job-shop scheduling

- Consider a small part of the car assembly, consists of 15 tasks
  - Install axles (front & back)
  - Affix all four wheels (right and left, front and back)
  - Tighten nuts for each wheel, affix hubcaps
  - Inspect the final assembly
- Represent the tasks with 15 variables:

$$X = \{Axle_F, Axle_B, Wheel_{RF}, Wheel_{LF}, Wheel_{RB}, Wheel_{LB}, Nuts_{RF}, Nuts_{LF}, Nuts_{RB}, Nuts_{LB}, Cap_{RF}, Cap_{LF}, Cap_{RB}, Cap_{LB}, Inspect\}$$

  - The value of each variable: the time that tasks starts
- **Precedence constraints** (between individual tasks)

$$T_1 + d_1 \leq T_2$$

T_1 must occur before T_2.
T_1 takes duration d_1 to complete.

Example: Job-shop scheduling

- Install the axles (10 min): They have to be in place before the wheels are put on

$$Axle_F + 10 \leq Wheel_{RF} \quad Axle_F + 10 \leq Wheel_{LF}$$
$$Axle_B + 10 \leq Wheel_{RB} \quad Axle_B + 10 \leq Wheel_{LB}$$

- Affix the wheels (1 min), tighten the nuts (2 min), and attach the hubcap (1 min):

$$Wheel_{RF} + 1 \leq Nuts_{RF} \quad Nuts_{RF} + 2 \leq Cap_{RF}$$
$$Wheel_{LF} + 1 \leq Nuts_{LF} \quad Nuts_{LF} + 2 \leq Cap_{LF}$$
$$Wheel_{RB} + 1 \leq Nuts_{RB} \quad Nuts_{RB} + 2 \leq Cap_{RB}$$
$$Wheel_{LB} + 1 \leq Nuts_{LB} \quad Nuts_{LB} + 2 \leq Cap_{LB}$$

Example: Job-shop scheduling

- **Disjunctive constraint**: $Axle_F$ and $Axle_B$ must not overlap in time
  - Either one comes first and the other does

$$(Axle_F + 10 \leq Axle_B) \textbf{ or } (Axle_B + 10 \leq Axle_F)$$

- Do inspection (3 min for each task): for every variable except *Inspect*, we add a constraint:

$$X + d_X \leq Inspect$$

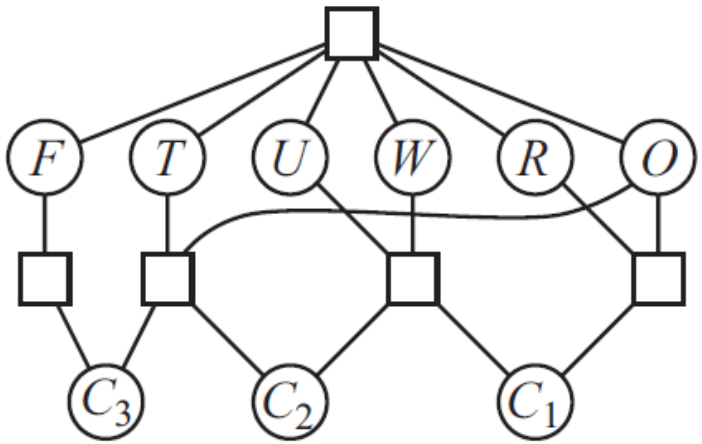
- Limit the domain of all variables (The whole assembly should be done in 30 min):

$$D_i = \{1, 2, 3, \cdots, 27\} \tag{1}$$

Constraints

- **Unary constraint**: restricts the value of a single variable
- **Binary constraint**: relates two variables
- **Global constraint**: involving an arbitrary number of variables
  - E.g.)**Cryptarithmetic** puzzles - $Alldiff(F, T, U, R, O)$

$$\begin{array}{r} T\ W\ O \\ +\ T\ W\ O \\ \hline F\ O\ U\ R \end{array}$$



$$O + O = R + 10 \cdot C_{10}$$
$$C_{10} + W + W = U + 10 \cdot C_{100}$$
$$C_{100} + T + T = O + 10 \cdot C_{1000}$$
$$C_{1000} = F$$

Additional constraints can be represented by **hypergraph**.

Constraint propagation: Inference in CSPs

- CSP algorithm has a choice between:
- **Search**: Choose a new variable assignment
- **Constraint propagation**: using the constraints to reduce the numbers of regal values for variables
  - may be interwined with search, or may be done as a preprocessing step, before search starts.

Constraint propagation: Local consistency

- **Local consistency**: Enforcing local consistency in each node and arc of a constraint graph eliminate inconsistent values throughout the graph.
- **Node consistency**: Satisfy the variables's unary constraints on their values. E.g.) $\langle (SA), SA \neq green \rangle$
- **Arc consistency**: Satisfy the variables's binary constraints.
  - For the constraint $Y = X^2$, we have $\langle (X, Y), \{(0,0), (1,1), (2,4), (3,9)\} \rangle$
  - But, For the map-coloring problem, arc consistency "do nothing":

$$\langle (SA, WA), \{(R,G), (R,B), (G,R), (G,B), (B,R), (B,G)\} \rangle$$

No matter what value you choose for SA, there is a valid value for WA.

Arc-consistent algorithm – AC-3

- After applying AC-3, either every arc is arc-consistent, or some variable has an empty domain, indicating that the CSP cannot be solved.

function AC-3(*csp*) **returns** false if an inconsistency is found and true otherwise
  inputs: *csp*, a binary CSP with components $(X,\ D,\ C)$
  local variables: *queue*, a queue of arcs, initially all the arcs in *csp*

  while *queue* is not empty **do**
    $(X_i,\ X_j) \leftarrow$ REMOVE-FIRST(*queue*)
    if REVISE(*csp*, $X_i,\ X_j$) **then**
      if size of $D_i\ =\ 0$ **then return** *false*
      for each X_k **in** X_i.NEIGHBORS - $\{X_j\}$ **do**
        add $(X_k,\ X_i)$ to *queue*
  return *true*

---

function REVISE(*csp*, $X_i,\ X_j$) **returns** true iff we revise the domain of X_i
  revised $\leftarrow$ *false*
  for each x **in** D_i **do**
    if no value y in D_j allows (x,y) to satisfy the constraint between X_i and X_j **then**
      delete x from D_i
      revised $\leftarrow$ *true*
  return *revised*

Path consistency

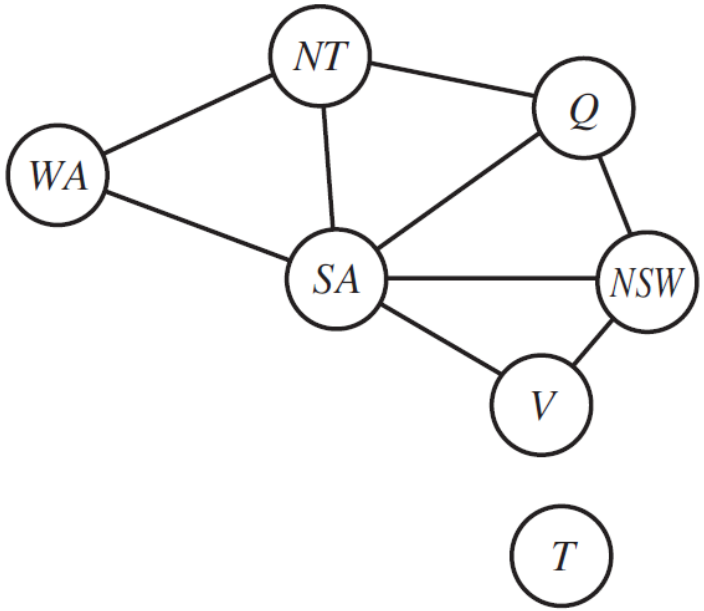
- Arc consistency: tightens down the domains (unary constraints) using the arcs (binary constraints)
- **Path consistency**: tightens the binary constraints by using implicit constraints that are inferred by looking at triples of variables.

Path consistency

A two-variable set $\{X_i, X_j\}$ is **path-consistent** with respect to a third variable X_m if, for every assignment $\{X_i = a, X_j = b\}$ consistent with the constraints on $\{X_i, X_j\}$, there is an assignment to X_m that satisfies the constraints on $\{X_i, X_m\}$ and $\{X_m, X_j\}$.

Path consistency: Example

- Coloring the Australia map with two colors.
- What is the set $\{WA, SA\}$ path consistent with respect to NT?



- There are only two: $\{WA = red, SA = blue\}$ and $\{WA = blue, SA = red\}$
- No valid choice for NT. No solution to this problem

K-consistency

K-consistency

CSP is k-consistent if, for any set of $k-1$ variables and for any consistent assignment to those variables, a consistent value can always be assigned to any k-th variable

- - 1-consistency: node consistency
  - 2-consistency: arc consistency
  - 3-consistency: path consistency

Strong K-consistency

A CSP is strongly k-consistent if it is k-consistent and is also $(k-1)$-consistent, $(k-2)$-consistent, $\cdots$, all the way down to 1-consistent.

- - Time complexity for finding a solution: $\mathcal{O}(n^2 d)$ to a find solution for strongly n-consistent CSP with n nodes
  - Time and space complexity for establishing n-consistency: exponential in n

Global consistency

- **Global consistency**: One involving an arbitrary number of variables (but not necessarily all variables)
  - For example, the *Alldiff* constraint: all the variables involved must have distinct values.
- Simple method of inconsistency detection for *Alldiff* constraints: if m variables are involved in the constraint with n possible distinct values, $m > n$, then the constraint cannot be satisfied.
- Example: Detecting inconsistency in $\{WA = red, NSW = red\}$
  - Consider SA, NT, and Q that are effectively connected by an *Alldiff* constraint.
  - After applying AC-3 with the partial assignment, the domain of each variable is reduced to $\{green, blue\}$.
  - But, $m > n$ $(3 > 2)$, so the *Alldiff* constraint is violated.

Example: Sudoku

- A Sudoku puzzle and its solution

	1	2	3	4	5	6	7	8	9
A			3		2		6		
B	9			3		5			1
C			1	8		6	4		
D			8	1		2	9		
E	7								8
F			6	7		8	2		
G			2	6		9	5		
H	8			2		3			9
I			5		1		3		

	1	2	3	4	5	6	7	8	9
A	4	8	3	9	2	1	6	5	7
B	9	6	7	3	4	5	8	2	1
C	2	5	1	8	7	6	4	9	3
D	5	4	8	1	3	2	9	7	6
E	7	2	9	5	6	4	1	3	8
F	1	3	6	7	9	8	2	4	5
G	3	7	2	6	8	9	5	1	4
H	8	1	4	2	5	3	7	6	9
I	6	9	5	4	1	7	3	8	2

- How far can arc consistency take us?
