Wumpus world: The current state of the world

- a square is *breezy*: a neighboring square has a pit
  a square is *smelly*: a neighboring square has a wumpus

$$
\begin{aligned}
B_{1,1} &\Leftrightarrow (P_{1,2} \vee P_{2,1}) \\
S_{1,1} &\Leftrightarrow (W_{1,2} \vee W_{2,1}) \\
&\dots
\end{aligned}
$$

- There is *at least* one wumpus.

$$W_{1,1} \vee W_{1,2} \vee \cdots \vee W_{4,3} \vee W_{4,4}$$

- There is *at most* one wumpus.

$$
\begin{aligned}
&\neg W_{1,1} \vee \neg W_{1,2} \\
&\neg W_{1,1} \vee \neg W_{1,3} \\
&\neg W_{1,1} \vee \neg W_{1,4} \\
&\dots \\
&\neg W_{4,3} \vee \neg W_{4,4}
\end{aligned}
$$

Associating propositions with time steps

- A percept should assert something *only about the current time*: E.g. $Stench^t$, $Breeze^t$, $Glitter^t$, etc.
  - Otherwise, suppose that there was no stench at the previous time, i.e., $\neg Stench$ was asserted. Then, if there is currently a stench, we cannot add $Stench$ at the current time, because the new assertion results in a contradiction.
- **Fluent**: refers to an aspect of the world that changes.
- **Atemporal variances**: symbols associated with permanent aspects of the world do not need a time superscript.
- For any time step t and any square $[x, y]$, we assert:

$$L^t_{x,y} \Leftarrow \left(Breeze^t \Leftrightarrow B_{x,y}\right)$$
$$L^t_{x,y} \Leftarrow \left(Stench^t \Leftrightarrow S_{x,y}\right)$$

Effect axioms

- Transition models on fluents: Fluents chance as the result of actions taken by the agent.
- **Effect axioms**: Specify the outcome of an action at the next time step.

$$L^0_{1,1} \wedge FacingEast^0 \wedge Forward^0 \Leftarrow (L^1_{2,1} \wedge \neg L^1_{1,1})$$

$$\ldots$$

Frame problem

- **Frame problem**: need to represent a long list of facts that are not changed by an action
- Suppose that the agent move *Forward* at time 0. Given effect axioms, we have $L^1_{2,1}$. Thus, $ASK(KB, L^1_{2,1}) = true$.
- However, $ASK(KB, HaveArrow^1) = false$: The agent cannot provie it still has the arrow now doesn't have it.
- Effect axioms only fail to state what remains *unchanged* as the result of an action.

Frame axioms

- **Frame axioms**: As one possible solution to the frame problem, we can add frame axioms that explicitly asserts all the propositions that remain the same.

$$Forward^t \Leftarrow (HaveArrow^t \Leftrightarrow HaveArrow^{t+1})$$
$$Forward^t \Leftarrow (WumpusAlive^t \Leftrightarrow WumpusAlive^{t+1})$$
$$\ldots$$

- **Representational frame problem**: With m actions and n fluents, the set of frame axioms is $\mathcal{O}(mn)$, being largely inefficient.
- Need to use **Locality**: Each action typically changes no more than some small number k of fluents, thus requiring to define $\mathcal{O}(mk)$, rather than $\mathcal{O}(mn)$.
- **Inferential frame problem**: The problem of projecting forward the results of t step plan of action in time $\mathcal{O}(kt)$ rather than $\mathcal{O}(nt)$ - The need to reason explicitly about things that don't change.

Successor-state axiom

- **Successor-state axiom**: Axioms about *fluents*. For each fluent F, a successor-state axiom defines F^{t+1} in terms of fluents at time t and the actions that may have occurred at time t, with the following schema:

$$F^{t+1} \Leftrightarrow ActionCausesF^t \vee \left(F^t \wedge \neg ActionCausesNotF^t\right)$$

- For *HaveArrow*

$$HaveArrow^{t+1} \Leftrightarrow \left(HaveArrow^t \wedge \neg Shoot^t\right)$$

- For the agent's location

$$\begin{aligned} L_{1,1}^{t+1} \quad \Leftrightarrow \quad & \left(L_{1,1}^t \wedge \left(\neg Forward^t \vee Bump^{t+1}\right)\right) \\ \vee \quad & \left(L_{1,2}^t \wedge \left(South^t \wedge Forward^t\right)\right) \\ \vee \quad & \left(L_{2,1}^t \wedge \left(West^t \wedge Forward^t\right)\right) \end{aligned}$$

Wumpus world: Question about the current state of the world

- Given the initial sequence of percepts and actions:

$$\begin{aligned}
&\neg Stench^0 \wedge \neg Breeze^0 \wedge \neg Glitter^0 \wedge \neg Bump^0 \wedge \neg Scream^0 \;;\; Forward^0 \\
&\neg Stench^1 \wedge Breeze^1 \wedge \neg Glitter^1 \wedge \neg Bump^1 \wedge \neg Scream^1 \;;\; TurnRight^1 \\
&\neg Stench^2 \wedge Breeze^2 \wedge \neg Glitter^2 \wedge \neg Bump^2 \wedge \neg Scream^2 \;;\; TurnRight^2 \\
&\neg Stench^3 \wedge Breeze^3 \wedge \neg Glitter^3 \wedge \neg Bump^3 \wedge \neg Scream^3 \;;\; Forward^3 \\
&\neg Stench^4 \wedge \neg Breeze^4 \wedge \neg Glitter^4 \wedge \neg Bump^4 \wedge \neg Scream^4 \;;\; TurnRight^4 \\
&\neg Stench^5 \wedge \neg Breeze^5 \wedge \neg Glitter^5 \wedge \neg Bump^5 \wedge \neg Scream^5 \;;\; Forward^5 \\
&Stench^6 \wedge \neg Breeze^6 \wedge \neg Glitter^6 \wedge \neg Bump^6 \wedge \neg Scream^6
\end{aligned}$$

- Now, we have $ASK(KB, L^6_{1,2}) = true$, $ASK(KB, W_{1,3}) = true$, $ASK(KB, P_{1,3}) = true$.
- We can also define the additional axiom to check whether a square is OK:

$$OK^t_{x,y} \Leftrightarrow \neg P_{x,y} \wedge \neg\neg \left(W_{x,y} \wedge WumpusAlive^t\right)$$

Then, we have $ASK(KB, OK^6_{2,2}) = true$.

Qualification problem

- We need to confirm *all the necessary preconditions* of an action hold for it to have its intended effect.
  - E.g.: the *Forward* action moves the agent ahead unless there is a wall in the way, but there are many other unusual exceptions that could cause the action to fail: the agent might trip and fall, be stricken with a heart attack, be carried away by giant bats, etc.
- Specifying all these exceptions is called the **qualification problem**: No complete solution within logic, raising a designing problem on knowledge base.

Hybrid agent: combine logical inference with problem-solving ability

function HYBRID-WUMPUS-AGENT(*percept*) **returns** an *action*
  inputs: *percept*, a list, [*stench*,*breeze*,*glitter*,*bump*,*scream*]
  persistent: KB, a knowledge base, initially the atemporal "wumpus physics"
    t, a counter, initially 0, indicating time
    plan, an action sequence, initially empty

  TELL(KB, MAKE-PERCEPT-SENTENCE(*percept*, t))
  TELL the KB the temporal "physics" sentences for time t
  $safe \leftarrow \{[x, y] : \text{ASK}(KB, OK^t_{x,y}) = true\}$
  if ASK(KB, $Glitter^t$) $= true$ **then**
    $plan \leftarrow$ [*Grab*] + PLAN-ROUTE(*current*, {[1,1]}, *safe*) + [*Climb*]
  if *plan* is empty **then**
    $unvisited \leftarrow \{[x, y] : \text{ASK}(KB, L^{t'}_{x,y}) = false \text{ for all } t' \leq t\}$
    $plan \leftarrow$ PLAN-ROUTE(*current*, $unvisited \cap safe$, *safe*)
  if *plan* is empty and ASK(KB, $HaveArrow^t$) $= true$ **then**
    $possible\_wumpus \leftarrow \{[x, y] : \text{ASK}(KB, \neg\, W_{x,y}) = false\}$
    $plan \leftarrow$ PLAN-SHOT(*current*, *possible_wumpus*, *safe*)
  if *plan* is empty **then** // no choice but to take a risk
    $not\_unsafe \leftarrow \{[x, y] : \text{ASK}(KB, \neg\, OK^t_{x,y}) = false\}$
    $plan \leftarrow$ PLAN-ROUTE(*current*, $unvisited \cap not\_unsafe$, *safe*)
  if *plan* is empty **then**
    $plan \leftarrow$ PLAN-ROUTE(*current*, {[1, 1]}, *safe*) + [*Climb*]
  $action \leftarrow$ POP(*plan*)
  TELL(KB, MAKE-ACTION-SENTENCE(*action*, t))
  $t \leftarrow t + 1$
  return *action*

Hybrid agent: combine logical inference with problem-solving ability

function PLAN-ROUTE(*current*,*goals*,*allowed*) **returns** an action sequence
  inputs: *current*, the agent's current position
    goals, a set of squares; try to plan a route to one of them
    allowed, a set of squares that can form part of the route

  problem ← ROUTE-PROBLEM(*current*, *goals*,*allowed*)
  return A*-GRAPH-SEARCH(*problem*)

Logical state estimation

- The weakness in the algorithm of hybrid agent: as time goes by, the computational expense involved in the calls to *ASK* goes up and up. This is because the required inferences have to go back further and further in time and involve more and more proposition symbols.
- **Belief state**: some representation of the set of all possible current states of the world. Here, the belief state is a logical sentence.

$$WumpusAlive^1 \wedge L^1_{2,1} \wedge B_{2,1} \wedge (P_{3,1} \vee P_{2,2})$$

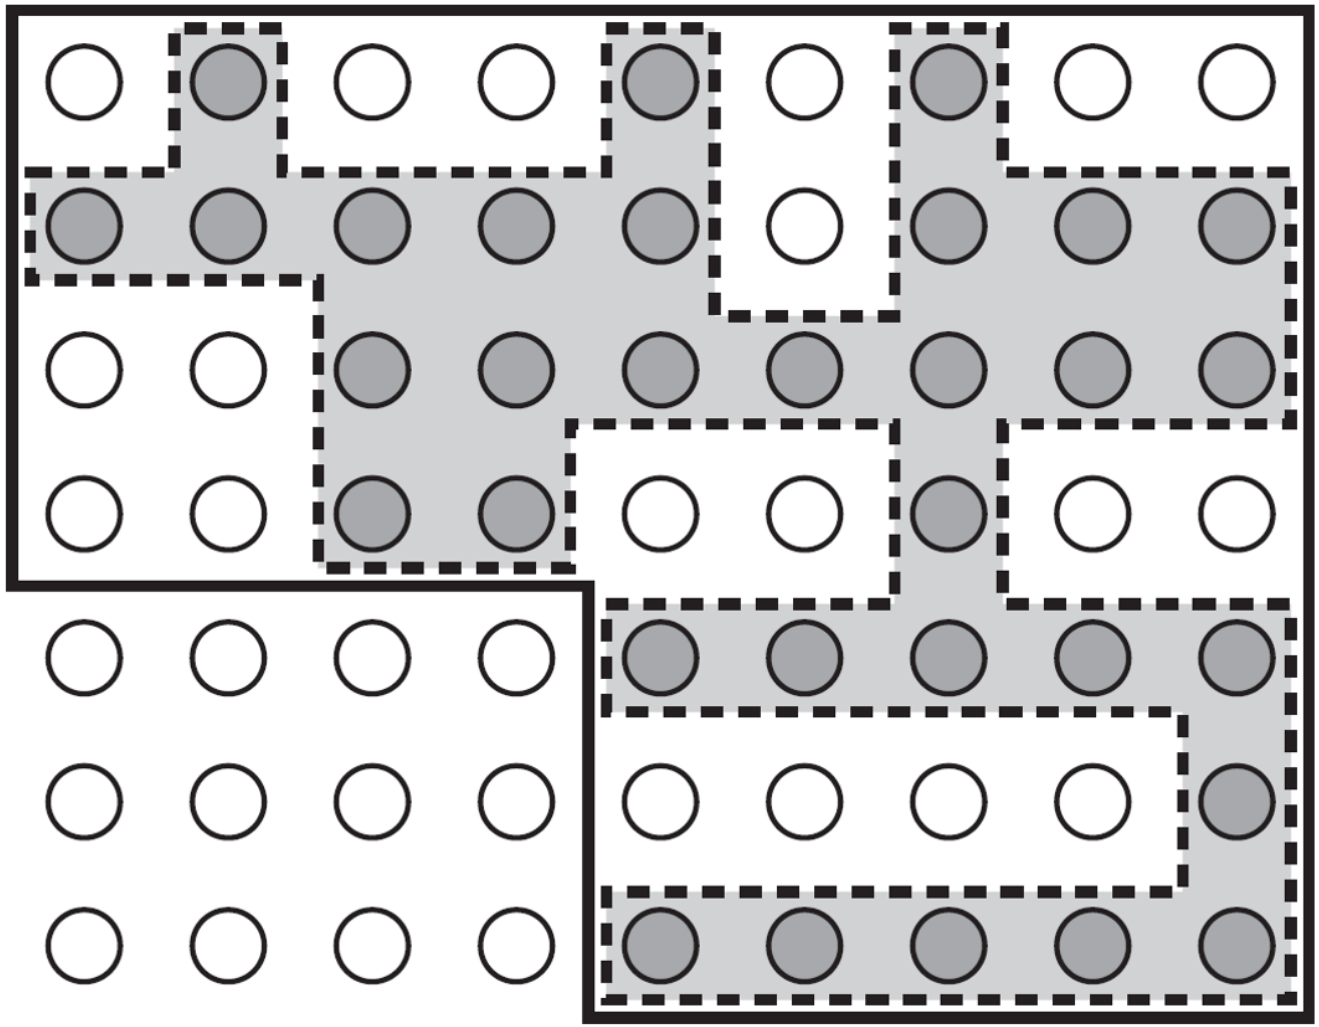
- **State estimation**: the process of updating the belief state as new percepts arrive.

Approximate Logical state estimation

- Maintaining an exact belief state as a logical formula: *not tractable*.
  - For n fluent symbols for time t, there are 2^n possible states and 2^{2^n} belief states.
- **Approximate state estimation**: Represent belief states as conjunctions of literals, 1-CNF formulas.
  - The agent program tries to prove X^t and $\neg X^t$ for each symbol X_t, given the belief state at $t-1$.
  - The conjunction of provable literals becomes the new belief state, and the previous belief state is discarded.

Approximate Logical state estimation

- the 1-CNF belief state acts as a simple outer envelope: The set of possible states represented by the 1-CNF belief state includes all states that are in fact possible given the full percept history.



Making plans by propositional inference

- 1) Construct a sentence that includes.
  - $Init^0$, a collection of assertions about the initial state;
  - $Transition^1, \cdots, Transition^t$, the successor-state axioms for all possible actions at each time up to some maximum time t;
  - the assertion that the goal is achieved at time t: $HaveGold^t \wedge ClimbedOut^t$.
- 2) Present the whole sentence to a SAT solver. If the solver finds a satisfying model, then the goal is achievable; if the sentence is unsatisfiable, then the planning problem is impossible.
- 3) Assuming a model is found, extract from the model those variables that represent actions and are assigned *true*. The resulting model is provided as a plan to achieve the goals.

Making plans by propositional inference

function SATPLAN($init$, $transition$, $goal$, $T_{\max}$) **returns** solution or failure
  inputs: $init$, $transition$, $goal$, constitute a description of the problem
    $T_{\max}$, an upper limit for plan length

  for $t = 0$ **to** $T_{\max}$ **do**
    $cnf \leftarrow$ TRANSLATE-TO-SAT($init$, $transition$, $goal$, t)
    $model \leftarrow$ SAT-SOLVER(cnf)
    if $model$ is not null **then**
      return EXTRACT-SOLUTION($model$)
  return *failure*

SATPLAN: Entailment vs. Satisfiability

- Suppose that $L^0_{1,1}$, we didn't tell the agenet that it can'ts be in two places at once. Then, $L^0_{2,1}$ is unknown
  - For entailment, the unknown literal $L^0_{2,1}$ *cannot* be used in a proof
  - For satisfiability, the unknown literal $L^0_{2,1}$ *can* be set to whatever value helps to make the goal true.
- Thus, *SATPLAN*: a good debugging tool for KBs because it reveals places where knowledge is missing.
  - E.g.: we can fix the knowledge base by asserting that, at each time step, the agent is in exactly one location.

SATPLAN: On satifiability issue - Additional axioms

- 1. *SATPLAN* finds models with *impossible actions*, such as shooting with no arrow.
  - **Precondition axioms**: stating that an action occurrence requires the preconditions to be satisfied

$$Shoot^t \Leftarrow HaveArrow_t \tag{1}$$

- 2. *SATPLAN* finds the models with *multiple simultaneous actions*.
  - **Action exclusion axioms**: every pair of actions A_i^t and A_j^t, we add the axiom

$$\neg A_i^t \vee \neg A_j^t \tag{2}$$
