Policy Gradient II

Used Materials

- **Disclaimer**: Much of the material and slides for this lecture were borrowed from Rich Sutton's RL class and David Silver's Deep RL tutorial

Policy-Based Reinforcement Learning

- So far we approximated the value or action-value function using parameters θ (e.g. neural networks)

$$V_\theta(s) \approx V^\pi(s)$$
$$Q_\theta(s, a) \approx Q^\pi(s, a)$$

- A policy was generated directly from the value function e.g. using ε-greedy

- In this lecture we will directly parameterize the policy

$$\pi_\theta(s, a) = \mathbb{P}\left[a \mid s, \theta\right]$$

- We will focus again on model-free reinforcement learning

Policy Gradient Theorem

- The policy gradient theorem generalizes the likelihood ratio approach to multi-step MDPs
- Replaces instantaneous reward r with long-term value $Q^{\pi}(s,a)$
- Policy gradient theorem applies to start state objective, average reward and average value objective

---

- For any differentiable policy $\pi_\theta(s, a)$, the policy gradient is

$$\boxed{\nabla_\theta J(\theta) = \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a)\ Q^{\pi_\theta}(s,a)\right]}$$

Monte-Carlo Policy Gradient (REINFORCE)

- Update parameters by stochastic gradient ascent
- Using policy gradient theorem
- Using return G_t as an unbiased sample of $Q^{\pi_\theta}(s_t, a_t)$

$$\Delta\theta_t = \alpha G_t \nabla_\theta \log \pi_\theta(s_t, a_t)$$

REINFORCE, A Monte-Carlo Policy-Gradient Method (episodic)

Input: a differentiable policy parameterization $\pi(a|s, \boldsymbol{\theta}), \forall a \in \mathcal{A}, s \in \mathcal{S}, \boldsymbol{\theta} \in \mathbb{R}^n$
Initialize policy weights $\boldsymbol{\theta}$
Repeat forever:
    Generate an episode $S_0, A_0, R_1, \ldots, S_{T-1}, A_{T-1}, R_T$, following $\pi(\cdot|\cdot, \boldsymbol{\theta})$
    For each step of the episode $t = 0, \ldots, T-1$:
        $G_t \leftarrow$ return from step t
        $\boldsymbol{\theta} \leftarrow \boldsymbol{\theta} + \alpha\gamma^t G_t \nabla_{\boldsymbol{\theta}} \log \pi(A_t|S_t, \boldsymbol{\theta})$

Actor-Critic

- Monte-Carlo policy gradient still has high variance
- We can use a critic to estimate the action-value function:

$$Q_w(s, a) \approx Q^{\pi_\theta}(s, a)$$

- Actor-critic algorithms maintain two sets of parameters
  - Critic Updates action-value function parameters w
  - Actor Updates policy parameters θ, in direction suggested by critic

- Actor-critic algorithms follow an approximate policy gradient

$$\nabla_\theta J(\theta) \approx \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s, a)\ Q_w(s, a)\right]$$
$$\Delta\theta = \alpha \nabla_\theta \log \pi_\theta(s, a)\ Q_w(s, a)$$

Reducing Variance Using a Baseline

- We can subtract a baseline function B(s) from the policy gradient
- This can reduce variance, without changing expectation!

$$
\begin{aligned}
\mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a) B(s)\right] &= \sum_{s\in\mathcal{S}} d^{\pi_\theta}(s) \sum_a \nabla_\theta \pi_\theta(s,a) B(s) \\
&= \sum_{s\in\mathcal{S}} d^{\pi_\theta} B(s) \nabla_\theta \underbrace{\sum_{a\in\mathcal{A}} \pi_\theta(s,a)}_{\text{equals 1}} \\
&= 0
\end{aligned}
$$

Function of state s, but
not action a

- A good baseline is the state value function $B(s) = V^{\pi_\theta}(s)$

Reducing Variance Using a Baseline

- We can subtract a baseline function B(s) from the policy gradient
- This can reduce variance, without changing expectation!

$$\mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s, a) B(s)\right] = 0$$

- A good baseline is the state value function $B(s) = V^{\pi_\theta}(s)$
- So we can rewrite the policy gradient using the advantage function:

$$A^{\pi_\theta}(s, a) = Q^{\pi_\theta}(s, a) - V^{\pi_\theta}(s)$$

$$\nabla_\theta J(\theta) = \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s, a) \; A^{\pi_\theta}(s, a)\right]$$

- Note that it is the exact same policy gradient:

$$\boxed{\nabla_\theta J(\theta) = \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s, a) \; Q^{\pi_\theta}(s, a)\right]}$$

Estimating the Advantage Function

- The advantage function can significantly reduce variance of policy gradient
- So the critic should really estimate the advantage function
- For example, by estimating both $V^{\pi_\theta}(s)$ and $Q^{\pi_\theta}(s, a)$
- Using two function approximators and two parameter vectors:

$$
\begin{aligned}
V_v(s) &\approx V^{\pi_\theta}(s) \\
Q_w(s, a) &\approx Q^{\pi_\theta}(s, a) \\
A(s, a) &= Q_w(s, a) - V_v(s)
\end{aligned}
$$

- And updating both value functions by e.g. TD learning

Dueling Networks

- Split Q-network into two channels
- Action-independent value function V(s,v)
- Action-dependent advantage function A(s, a, w)

$$Q(s,a) = V(s,v) + A(s,a,\mathbf{w})$$

- Advantage function is defined as:

$$A^{\pi}(s,a) = Q^{\pi}(s,a) - V^{\pi}(s).$$

Wang et.al., ICML, 2016

Estimating the Advantage Function

- For the true value function $V^{\pi_\theta}(s)$ the TD error:

$$\delta^{\pi_\theta} = r + \gamma V^{\pi_\theta}(s') - V^{\pi_\theta}(s)$$

  is an unbiased estimate of the advantage function:

$$\begin{aligned}\mathbb{E}_{\pi_\theta}\left[\delta^{\pi_\theta} | s, a\right] &= \mathbb{E}_{\pi_\theta}\left[r + \gamma V^{\pi_\theta}(s') | s, a\right] - V^{\pi_\theta}(s) \\ &= Q^{\pi_\theta}(s, a) - V^{\pi_\theta}(s) \\ &= A^{\pi_\theta}(s, a)\end{aligned}$$

- So we can use the TD error to compute the policy gradient

$$\nabla_\theta J(\theta) = \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s, a)\ \delta^{\pi_\theta}\right]$$

- Remember the policy gradient

$$\nabla_\theta J(\theta) = \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s, a)\ A^{\pi_\theta}(s, a)\right]$$

Estimating the Advantage Function

- For the true value function $V^{\pi_\theta}(s)$ the TD error:

$$\delta^{\pi_\theta} = r + \gamma V^{\pi_\theta}(s') - V^{\pi_\theta}(s)$$

  is an unbiased estimate of the advantage function

- So we can use the TD error to compute the policy gradient

$$\nabla_\theta J(\theta) = \mathbb{E}_{\pi_\theta} \left[\nabla_\theta \log \pi_\theta(s,a) \; \delta^{\pi_\theta} \right]$$

- In practice we can use an approximate TD error

$$\delta_v = r + \gamma V_v(s') - V_v(s)$$

- This approach only requires one set of critic parameters v

Critic

- Critic can estimate value function $V_v(s)$ from various targets. For example, from previous lectures:

- For MC, the target is the return G_t

$$\Delta \mathrm{v} = \alpha(G_t - V_{\mathrm{v}}(s_t))\nabla_{\mathrm{v}} V_{\mathrm{v}}(s)$$

- V_v can be a deep neural network with parameters v.

- For TD(0), the target is the TD target $r + \gamma V(s')$

$$\Delta \mathrm{v} = \alpha(r_{t+1} + \gamma V_{\mathrm{v}}(s_{t+1}) - V_{\mathrm{v}}(s_t))\nabla_{\mathrm{v}} V_{\mathrm{v}}(s)$$

- So critic is updated to minimize MSE w.r.t. target, given by MC or TD(0)

$$(V^{\pi_\theta}(s_t) - V_{\mathrm{v}}(s_t))^2$$

Actor

- The policy gradient can also be estimated as follows:

$$\nabla_\theta J(\theta) = \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a)\ A^{\pi_\theta}(s,a)\right]$$

- Monte-Carlo policy gradient uses error from complete return

$$\Delta\theta = \alpha(G_t - V_v(s_t))\nabla_\theta \log \pi_\theta(s_t, a_t)$$

- Actor-critic policy gradient uses the one-step TD error

$$\Delta\theta = \alpha(r + \gamma V_v(s_{t+1}) - V_v(s_t))\nabla_\theta \log \pi_\theta(s_t, a_t)$$

Advantage Actor-Critic Algorithm

One-step Actor-Critic (episodic)

Input: a differentiable policy parameterization $\pi(a|s,\boldsymbol{\theta}), \forall a \in \mathcal{A}, s \in \mathcal{S}, \boldsymbol{\theta} \in \mathbb{R}^n$
Input: a differentiable state-value parameterization $\hat{v}(s,\mathbf{w}), \forall s \in \mathcal{S}, \mathbf{w} \in \mathbb{R}^m$
Parameters: step sizes $\alpha > 0$, $\beta > 0$

Initialize policy weights $\boldsymbol{\theta}$ and state-value weights $\mathbf{w}$
Repeat forever:
  Initialize S (first state of episode)
  $I \leftarrow 1$
  While S is not terminal:
    $A \sim \pi(\cdot|S,\boldsymbol{\theta})$
    Take action A, observe S', R
    $\delta \leftarrow R + \gamma \hat{v}(S',\mathbf{w}) - \hat{v}(S,\mathbf{w})$ (if S' is terminal, then $\hat{v}(S',\mathbf{w}) \doteq 0$)
    $\mathbf{w} \leftarrow \mathbf{w} + \beta\,\delta\,\nabla_{\mathbf{w}} \hat{v}(S,\mathbf{w})$
    $\boldsymbol{\theta} \leftarrow \boldsymbol{\theta} + \alpha I \delta \nabla_{\boldsymbol{\theta}} \log \pi(A|S,\boldsymbol{\theta})$
    $I \leftarrow \gamma I$
    $S \leftarrow S'$

So Far: Summary of PG Algorithms

- The policy gradient has many equivalent forms

$$
\begin{aligned}
\nabla_\theta J(\theta) &= \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a)\, G_t\right] && \text{REINFORCE} \\
&= \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a)\; Q^w(s,a)\right] && \text{Q Actor-Critic} \\
&= \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a)\; A^w(s,a)\right] && \text{Advantage Actor-Critic} \\
&= \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a)\; \delta\right] && \text{TD Actor-Critic}
\end{aligned}
$$

- Each leads a stochastic gradient ascent algorithm

- Critic uses policy evaluation (e.g. MC or TD learning) to estimate $Q^\pi(s,a)$, $A^\pi(s,a)$ or $V^\pi(s)$

Bias in Actor-Critic Algorithms

- Approximating the policy gradient introduces bias

$$Q_w(s, a) \approx Q^{\pi_\theta}(s, a)$$

- A biased policy gradient may not find the right solution
- Luckily, if we choose value function approximation carefully
- Then we can avoid introducing any bias
- i.e. we can still follow the exact policy gradient

Compatible Function Approximation

- If the following two conditions are satisfied:

  1. Value function approximator is compatible to the policy

$$\boxed{\nabla_w Q_w(s,a) = \nabla_\theta \log \pi_\theta(s,a)}$$

  2 Value function parameters w minimize the mean-squared error

$$\boxed{\varepsilon = \mathbb{E}_{\pi_\theta}\left[\left(Q^{\pi_\theta}(s,a) - Q_w(s,a)\right)^2\right]}$$

- Then the policy gradient is exact,

$$\boxed{\nabla_\theta J(\theta) = \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a)\ Q_w(s,a)\right]}$$

- Remember:

$$\boxed{\nabla_\theta J(\theta) = \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a)\ Q^{\pi_\theta}(s,a)\right]}$$

Proof

- If w is chosen to minimize mean-squared error, gradient of ε w.r.t. w must be zero,

$$
\begin{aligned}
\nabla_w \varepsilon &= 0 \\
\mathbb{E}_{\pi_\theta}\left[(Q^\theta(s,a) - Q_w(s,a))\nabla_w Q_w(s,a)\right] &= 0 \\
\mathbb{E}_{\pi_\theta}\left[(Q^\theta(s,a) - Q_w(s,a))\nabla_\theta \log \pi_\theta(s,a)\right] &= 0 \\
\mathbb{E}_{\pi_\theta}\left[Q^\theta(s,a)\nabla_\theta \log \pi_\theta(s,a)\right] &= \mathbb{E}_{\pi_\theta}\left[Q_w(s,a)\nabla_\theta \log \pi_\theta(s,a)\right]
\end{aligned}
$$

- So $Q_w(s, a)$ can be substituted directly into the policy gradient,

$$
\nabla_\theta J(\theta) = \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a) Q_w(s,a)\right]
$$

Alternative Policy Gradient Directions

- Gradient ascent algorithms can follow any ascent direction
- A good ascent direction can significantly speed convergence
- Also, a policy can often be reparametrized without changing action probabilities
- For example, increasing score of all actions in a softmax policy
- The vanilla gradient is sensitive to these reparametrizations

Natural Policy Gradient

- The natural policy gradient is parametrzsation independent
- it finds ascent direction that is closest to vanilla gradient, when changing policy by a small, fixed amount

$$\nabla_\theta^{nat} \pi_\theta(s, a) = G_\theta^{-1} \nabla_\theta \pi_\theta(s, a)$$

- where G_θ is the Fisher information matrix

$$G_\theta = \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s, a) \nabla_\theta \log \pi_\theta(s, a)^T\right]$$

Natural Actor-Critic

- Using compatible function approximation,

$$\nabla_w A_w(s, a) = \nabla_\theta \log \pi_\theta(s, a)$$

- The natural policy gradient simplifies,

$$\begin{aligned}
\nabla_\theta J(\theta) &= \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s, a) A^{\pi_\theta}(s, a)\right] \\
&= \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s, a) \nabla_\theta \log \pi_\theta(s, a)^T w\right] \\
&= G_\theta w
\end{aligned}$$

$$\nabla_\theta^{nat} J(\theta) = w$$

Under linear model:

$$A^{\pi_\theta}(s, a) = \phi(s)^\top \mathrm{w}$$

- i.e. update actor parameters in direction of critic parameters

Summary of Policy Gradient Algorithms

- The policy gradient has many equivalent forms

$$
\begin{aligned}
\nabla_\theta J(\theta) &= \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a)\, G_t\right] && \text{REINFORCE} \\
&= \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a)\; Q^w(s,a)\right] && \text{Q Actor-Critic} \\
&= \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a)\; A^w(s,a)\right] && \text{Advantage Actor-Critic} \\
&= \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a)\; \delta\right] && \text{TD Actor-Critic} \\
&= \mathbb{E}_{\pi_\theta}\left[\nabla_\theta \log \pi_\theta(s,a)\; \delta e\right] && \text{TD}(\lambda)\text{ Actor-Critic} \\
G_\theta^{-1} \nabla_\theta J(\theta) &= w && \text{Natural Actor-Critic}
\end{aligned}
$$

- Each leads a stochastic gradient ascent algorithm
- Critic uses policy evaluation (e.g. MC or TD learning) to estimate $Q^\pi(s,a)$, $A^\pi(s,a)$ or $V^\pi(s)$

Improving Action Recognition

- Consider performing action recognition in a video:

- Instead of processing each frame, we can process only a small piece of each frame.

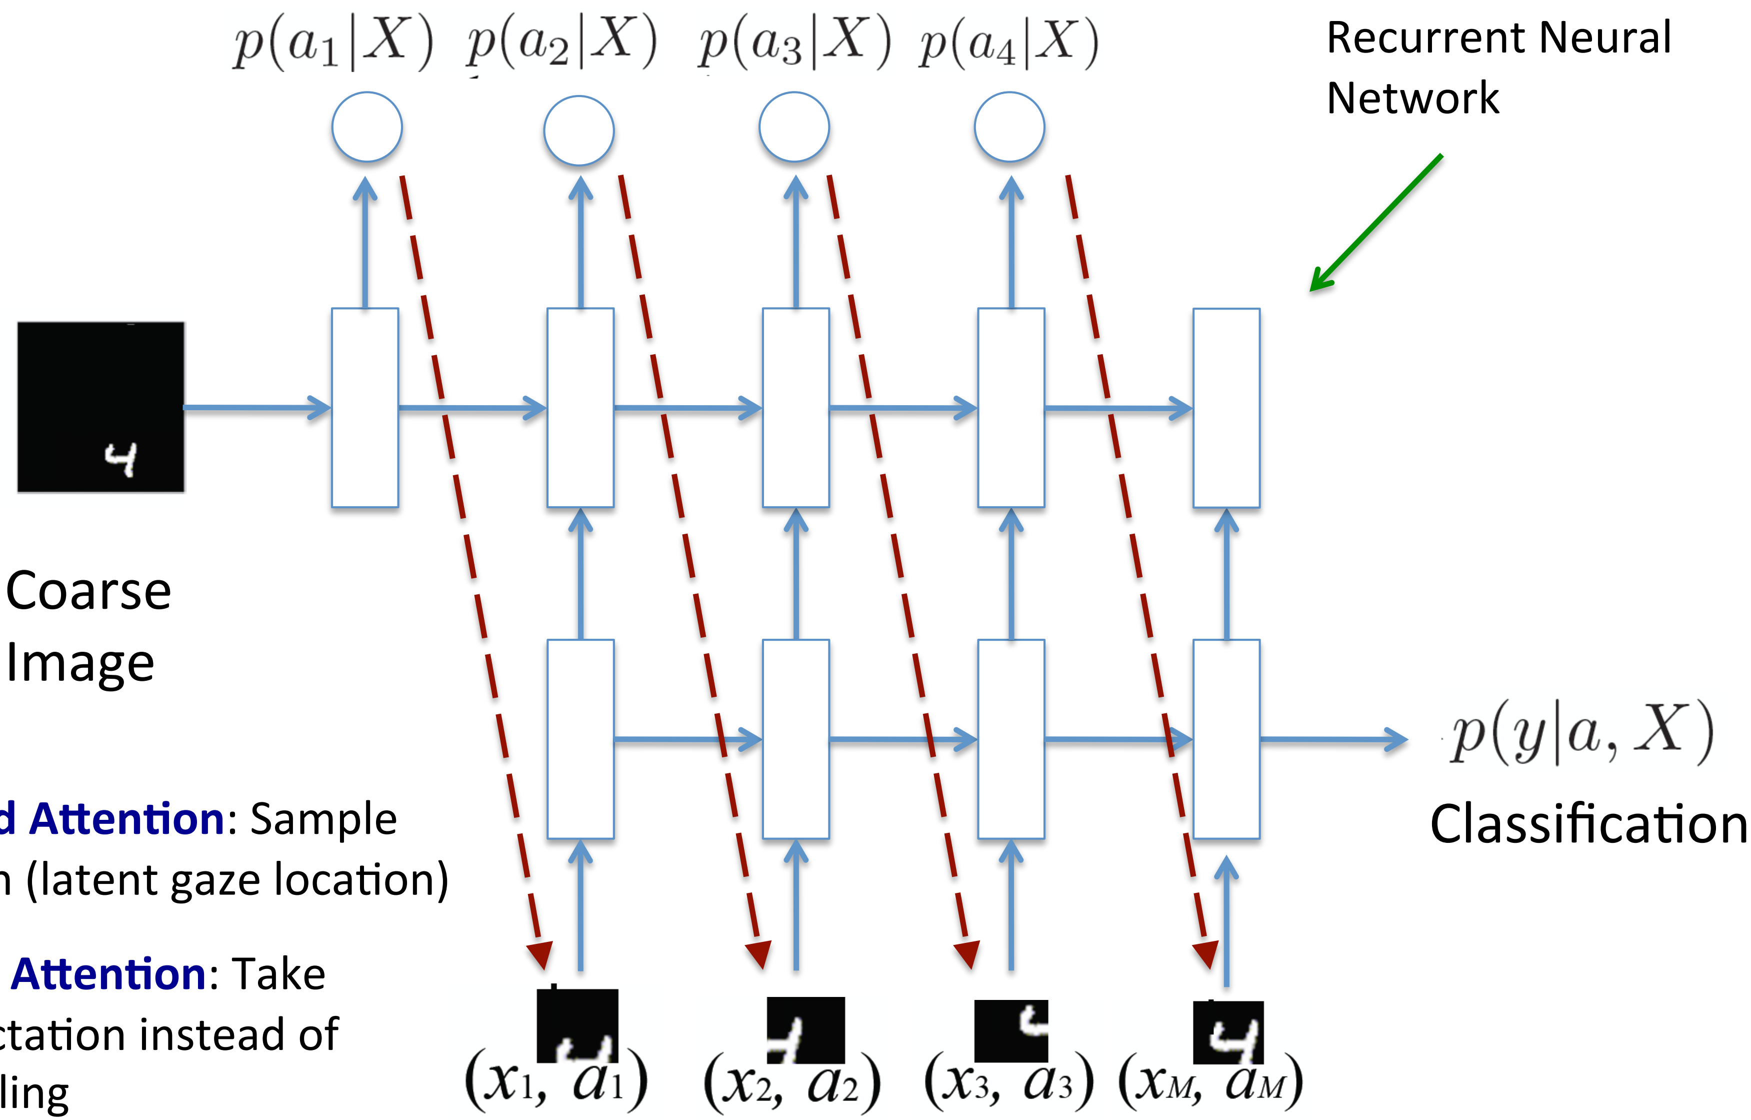
Improving Action Recognition

Cycling　Soccer juggling　Horse back riding　Basketball Shooting

Recurrent Attention Model

Sample action:

$\tilde{a}_1 \sim p(a_1|X) \qquad \tilde{a}_2 \sim p(a_2|X)$



- **Hard Attention**: Sample action (latent gaze location)
- **Soft Attention**: Take expectation instead of sampling

Model Setup

- We assume that we have a dataset with labels y for the supervised prediction task (e.g. object category).
- **Goal**: Learn an attention policy: The best locations to attend to are the ones which lead the model to predict the correct class.

Model Definition

- We aim to maximize the probability of correct class by marginalizing over the actions (or latent gaze locations):

$$\mathcal{LL} = \log p(y|X, W) = \log \sum_{a} p(a|X, W) p(y|a, X, W).$$

where

- W is the set of parameters of the recurrent network.
- a is a set of actions (latent gaze locations, scale).
- X: is the input (e.g. image, video frame).

For clarity of presentation, I will sometimes omit conditioning on W or X. It should be obvious from the context.

Variational Learning

- Previous approaches used variational lower bound:

$$\mathcal{LL} = \log \sum_a p(a|X,W)p(y|a,X,W) \geq$$

$$\sum_a q(a|y,X) \log p(y,a|X,W) + \mathcal{H}[q] = \mathcal{F}.$$

- Here $q(a|y,X)$ is some approximation to posterior over the gaze locations.

- In the case where q is the prior, $q(a|y,X) = p(a|X,W)$, the variational bound becomes:

$$\mathcal{F} = \sum_a p(a|X,W) \log p(y|a,X,W).$$

Ba et.al., ICLR 2015
Mnih et.al., NIPS 2014

REINFORCE

$$\mathcal{F} = \sum_a p(a|X, W) \log p(y|a, X, W).$$

- Derivatives w.r.t model parameters:

$$\frac{\partial \mathcal{F}}{\partial W} = \sum_a p(a|X, W) \left[\frac{\partial \log p(y|a, X, W)}{\partial W} + \underbrace{\log p(y|a, X, W)} \frac{\partial \log p(a|X, W)}{\partial W} \right].$$

Very bad term as it is unbounded.
Introduces high variance in the estimator.

- Need to introduce heuristics (e.g. replacing this term with a 0/1 discrete indicator function, which leads to REINFORCE algorithm of Williams, 1992).

Ba et.al., ICLR 2015
Mnih et.al., NIPS 2014

REINFORCE

$$\mathcal{F} = \sum_a p(a|X, W) \log p(y|a, X, W).$$

- Derivatives w.r.t model parameters:

$$\frac{\partial \mathcal{F}}{\partial W} = \sum_a p(a|X, W) \Big[\frac{\partial \log p(y|a, X, W)}{\partial W} + \log p(y|a, X, W) \frac{\partial \log p(a|X, W)}{\partial W} \Big].$$

- The stochastic estimator of the gradient is given by:

$$\frac{\partial \mathcal{F}}{\partial W} \approx \frac{1}{M} \sum_{m=1}^{M} \Big[\frac{\partial \log p(y|\tilde{a}^m, X, W)}{\partial W} + \log p(y|\tilde{a}^m, X, W) \frac{\partial \log p(\tilde{a}^m|X, W)}{\partial W} \Big].$$

where we draw M actions from the prior: $\tilde{a}^m \sim p(a|X, W)$.

MNIST Attention Demo

- Actions contain:
  - Location: 2-d Gaussian latent variable
  - Scale: 3-way softmax over 3 different scales
