Deep Reinforcement Learning and Control

Planning in Markov Decision Processes

Lecture 3, CMU 10703

Katerina Fragkiadaki

Markov Decision Process (MDP)

A **Markov Decision Process** is a tuple $(\mathcal{S}, \mathcal{A}, T, r, \gamma)$

- $\mathcal{S}$ is a finite set of states
- $\mathcal{A}$ is a finite set of actions
- T is a state transition probability function

$$T(s'|s,a) = \mathbb{P}[S_{t+1} = s' | S_t = s, A_t = a]$$

- r is a reward function

$$r(s,a) = \mathbb{E}[R_{t+1} | S_t = s, A_t = a]$$

- γ is a discount factor $\gamma \in [0, 1]$

Solving MDPs

- **Prediction**: Given an MDP $(\mathcal{S}, \mathcal{A}, T, r, \gamma)$ and a policy

$$\pi(a|s) = \mathbb{P}[A_t = a | S_t = s]$$

  find the state and action value functions.

- **Optimal control**: given an MDP $(\mathcal{S}, \mathcal{A}, T, r, \gamma)$, find the optimal policy (aka the planning problem). Compare with the learning problem with missing information about rewards/dynamics.

- We still consider finite MDPs (finite $\mathcal{S}$ and $\mathcal{A}$) with known dynamics!

Outline

- Policy iteration
- Value iteration
- Linear programming
- Asynchronous DP

Policy Evaluation

Policy evaluation: for a given policy π, compute the state value function

$$\mathrm{v}_\pi(s) = \mathbb{E}_\pi \left[R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \ldots | S_t = s \right]$$

where $\mathrm{v}_\pi(s)$ is implicitly given by the **Bellman equation**

$$\mathrm{v}_\pi(s) = \sum_{a \in \mathcal{A}} \pi(a|s) \left(r(s,a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s,a) \mathrm{v}_\pi(s') \right)$$

a system of $|\mathcal{S}|$ simultaneous equations.

MDPs to MRPs

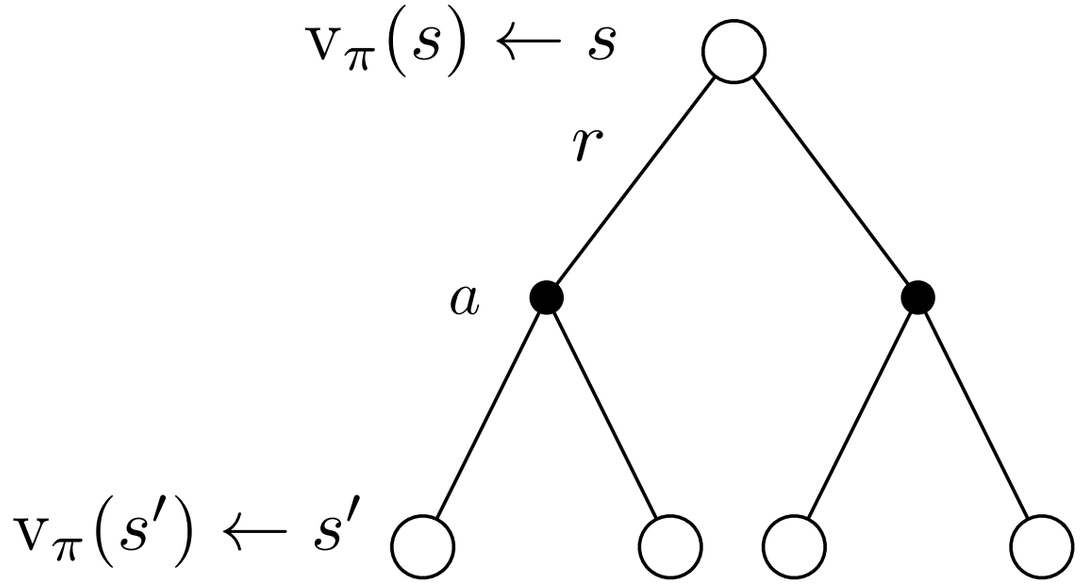
MDP under a fixed policy becomes **Markov Reward Process** (MRP)

$$
\begin{aligned}
\mathrm{v}_\pi(s) &= \sum_{a \in \mathcal{A}} \pi(a|s) \left(r(s,a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s,a) \mathrm{v}_\pi(s') \right) \\
&= \sum_{a \in \mathcal{A}} \pi(a|s) r(s,a) + \gamma \sum_{a \in \mathcal{A}} \pi(a|s) \sum_{s' \in \mathcal{S}} T(s'|s,a) \mathrm{v}_\pi(s') \\
&= r_s^\pi + \gamma \sum_{s' \in \mathcal{S}} T_{s's}^\pi \mathrm{v}_\pi(s')
\end{aligned}
$$

where $r_s^\pi = \sum_{a \in \mathcal{A}} \pi(a|s) r(s,a)$ and $T_{s's}^\pi = \sum_{a \in \mathcal{A}} \pi(a|s) T(s'|s,a)$

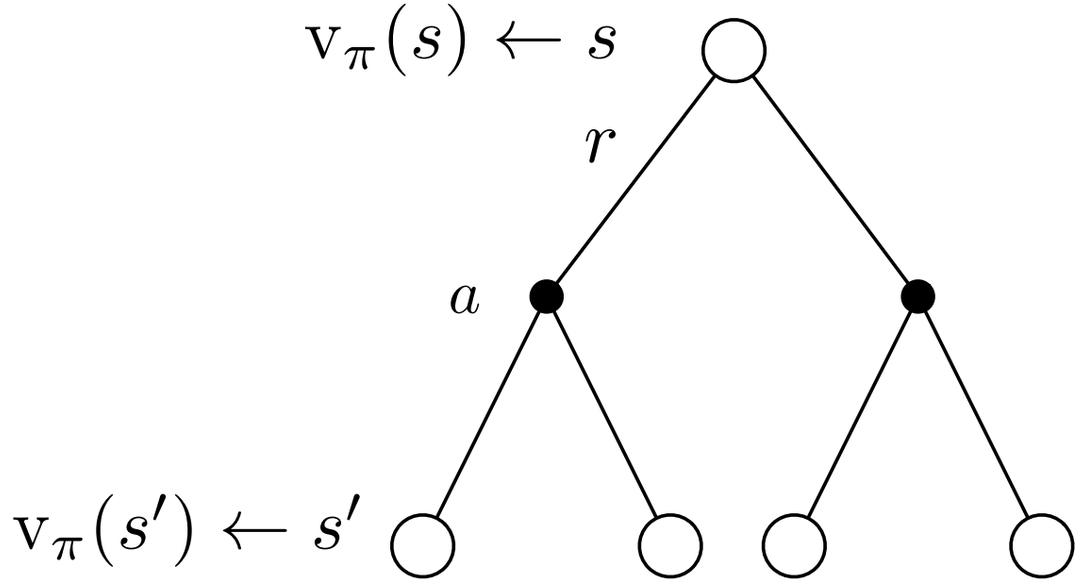
Back Up Diagram

MDP

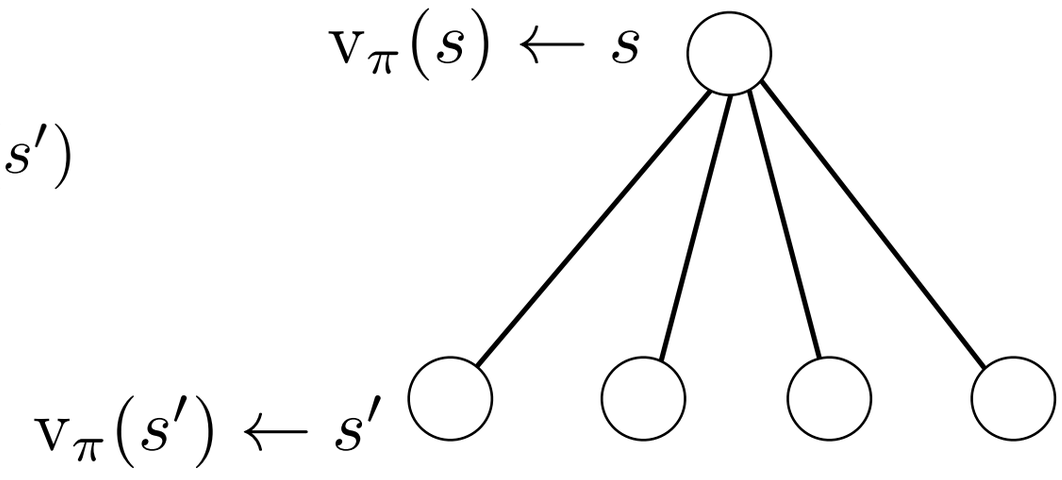


Back Up Diagram

MDP



MRP $\mathrm{v}_\pi(s) = r_s^\pi + \gamma \sum_{s' \in \mathcal{S}} T_{s's}^\pi \mathrm{v}_\pi(s')$



Matrix Form

The Bellman expectation equation can be written concisely using the induced MRP as

$$\mathrm{v}_\pi = r^\pi + \gamma T^\pi \mathrm{v}_\pi$$

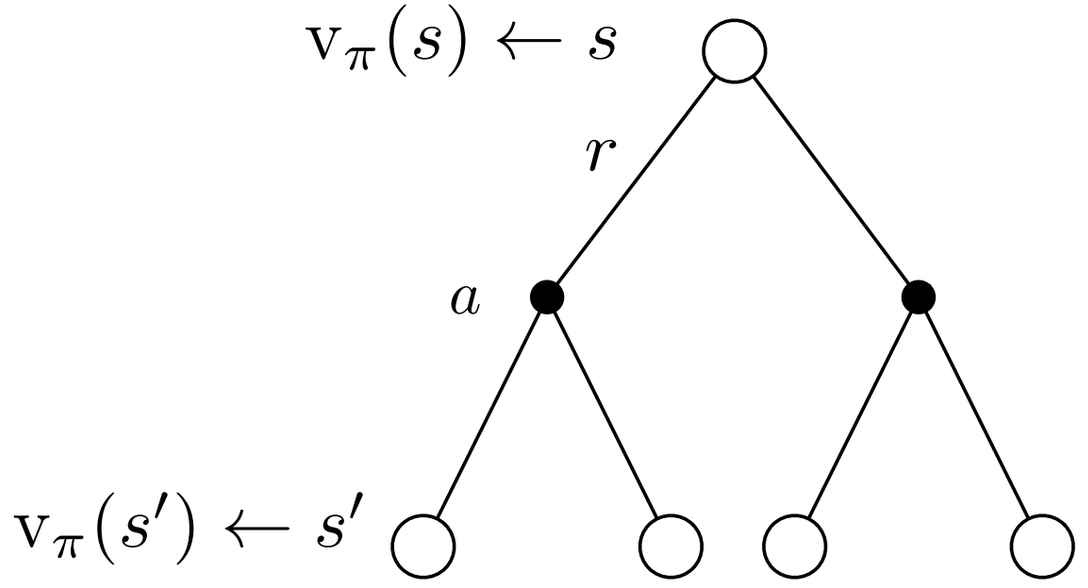
with direct solution

$$\mathrm{v}_\pi = (I - \gamma T^\pi)^{-1} r^\pi$$

of complexity $O(N^3)$

Iterative Methods: Recall the Bellman Equation

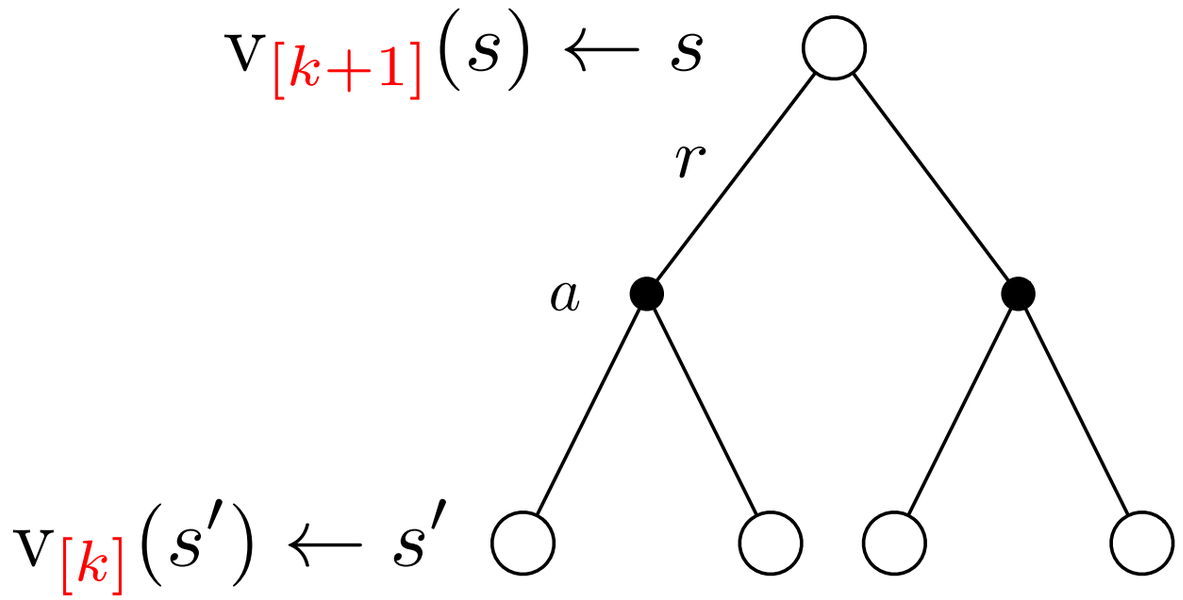
$$\mathrm{v}_\pi(s) = \sum_{a \in \mathcal{A}} \pi(a|s) \left(r(s,a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s,a) \mathrm{v}_\pi(s') \right)$$



Iterative Methods: Backup Operation

Given an expected value function at iteration *k*, we back up the expected value function at iteration *k+1:*

$$\mathrm{v}_{[k+1]}(s) = \sum_{a \in \mathcal{A}} \pi(a|s) \left(r(s,a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s,a) \mathrm{v}_{[k]}(s') \right)$$



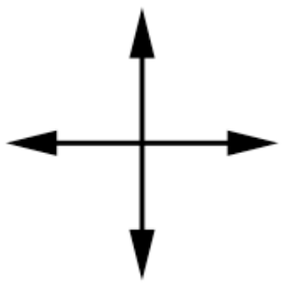
Iterative Methods: Sweep

A **sweep** consists of applying the backup operation $\mathrm{v} \rightarrow \mathrm{v}'$ for all the states in $\mathcal{S}$

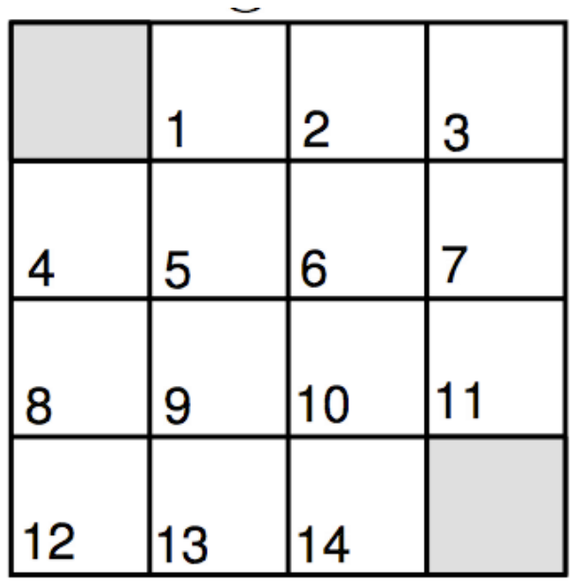
Applying the back up operator iteratively

$$\mathrm{v}_{[0]} \rightarrow \mathrm{v}_{[1]} \rightarrow \mathrm{v}_{[2]} \rightarrow \ldots \mathrm{v}_{\pi}$$

A Small-Grid World



actions



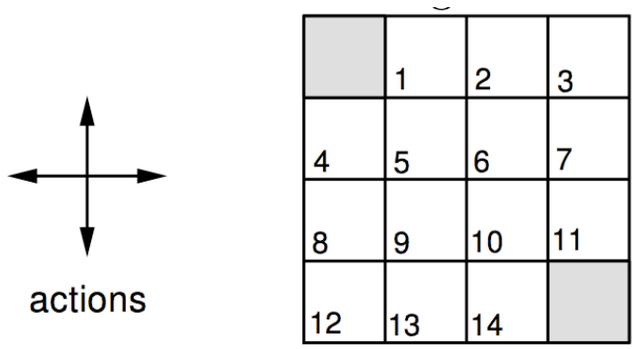
$R = -1$
on all transitions

$\gamma = 1$

- An undiscounted episodic task
- Nonterminal states: 1, 2, … , 14
- Terminal state: one, shown in shaded square
- Actions that would take the agent off the grid leave the state unchanged
- Reward is -1 until the terminal state is reached

Iterative Policy Evaluation

Policy π, an equiprobable random action



- An undiscounted episodic task

Contraction Mapping Theorem

An operator F on a normed vector space $\mathcal{X}$ is a γ**-contraction**, for $0 < \gamma < 1$, provided for all $x, y \in \mathcal{X}$

$$||T(x) - T(y)|| \leq \gamma ||x - y||$$

Theorem (Contraction mapping)
For a γ-contraction F in a complete normed vector space $\mathcal{X}$

- F converges to a unique fixed point in $\mathcal{X}$
- at a linear convergence rate γ

Remark. In general we only need metric (vs normed) space

Value Function Sapce

- Consider the vector space V over value functions
- There are $|\mathcal{S}|$ dimensions
- Each point in this space fully specifies a value function $\mathrm{v}(s)$
- Bellman backup brings value functions closer in this space?
- And therefore the backup must converge to a unique solution

Value Function ∞-Norm

- We will measure distance between state-value functions u and v by the ∞-norm
- i.e. the largest difference between state values,

$$||\mathrm{u} - \mathrm{v}||_\infty = \max_{s \in \mathcal{S}} |\mathrm{u}(s) - \mathrm{v}(s)|$$

Bellman Expectation Backup is a Contraction

- Define the Bellman expectation backup operator

$$F^{\pi}(\mathrm{v}) = r^{\pi} + \gamma T^{\pi}\mathrm{v}$$

- This operator is a γ-contraction, i.e. it makes value functions closer by at least γ,

$$\begin{aligned}
||F^{\pi}(\mathrm{u}) - F^{\pi}(\mathrm{v})||_{\infty} &= ||(r^{\pi} + \gamma T^{\pi}\mathrm{u})||_{\infty} - ||(r^{\pi} + \gamma T^{\pi}\mathrm{v})||_{\infty} \\
&= ||\gamma T^{\pi}(\mathrm{u} - \mathrm{v})||_{\infty} \\
&\leq ||\gamma T^{\pi}||\mathrm{u} - \mathrm{v}||_{\infty}||_{\infty} \\
&\leq \gamma||\mathrm{u} - \mathrm{v}||_{\infty}
\end{aligned}$$

Convergence of Iter. Policy Evaluation and Policy Iteration

- The Bellman expectation operator F^π has a unique fixed point
- v_π is a fixed point of F^π (by Bellman expectation equation)
- By contraction mapping theorem
- Iterative policy evaluation converges on v_π

Policy Improvement

- Suppose we have computed v_π for a deterministic policy π
- For a given state s, would it be better to do an action $a \neq \pi(s)$?
- It is better to switch to action a for state s if and only if

$$q_\pi(s, a) > \mathrm{v}_\pi(s)$$

- And we can compute $q_\pi(s, a)$ from v_π by:

$$\begin{aligned} q_\pi(s, a) &= \mathbb{E}[R_{t+1} + \gamma \mathrm{v}_\pi(S_{t+1}) | S_t = s, A_t = a] \\ &= r(s, a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s, a) \mathrm{v}_\pi(s') \end{aligned}$$

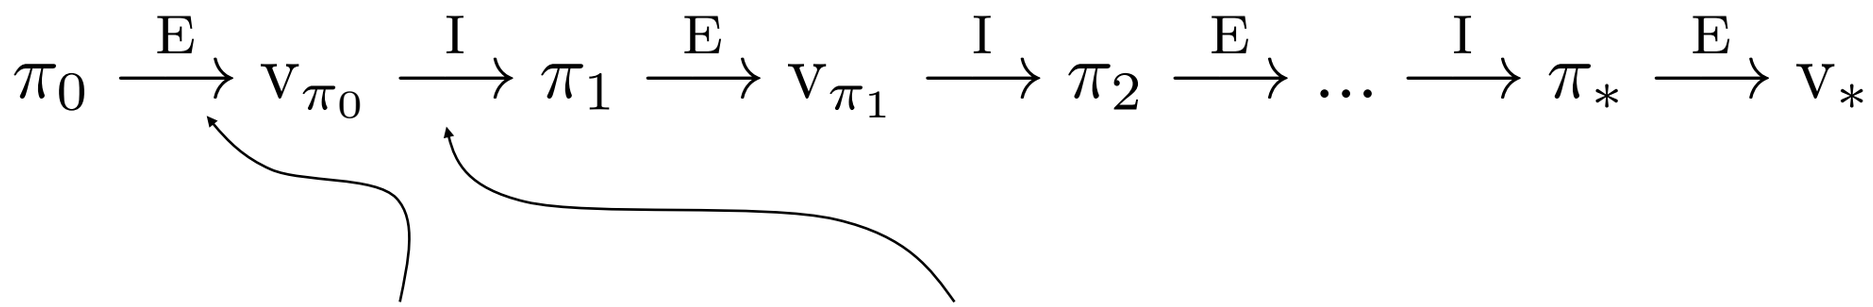
Policy Improvement Cont.

- Do this for all states to get a new policy $\pi' \geq \pi$ that is greedy with respect to v_π:

$$\begin{aligned}\pi'(s) &= \arg\max_a q_\pi(s,a) \\ &= \arg\max_a \mathbb{E}[R_{t+1} + \gamma \mathrm{v}_\pi(s') | S_t = s, A_t = a] \\ &= \arg\max r(s,a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s,a)\mathrm{v}_\pi(s')\end{aligned}$$

- What if the policy is unchanged by this?
  - Then the policy must be optimal!

Policy Iteration



Policy Iteration

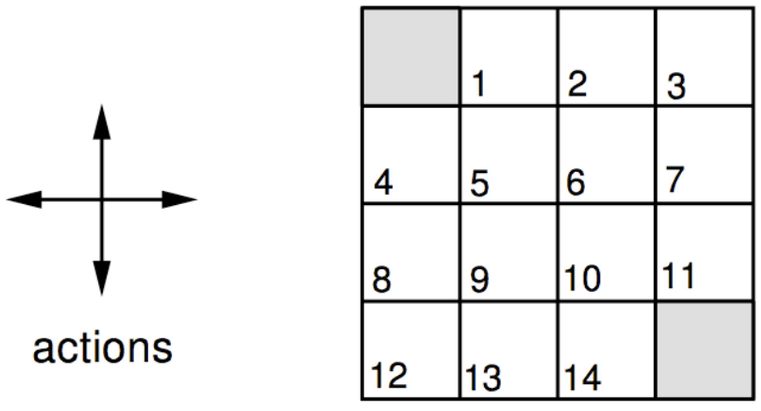
1. Initialization
   $V(s) \in \mathbb{R}$ and $\pi(s) \in \mathcal{A}(s)$ arbitrarily for all $s \in \mathcal{S}$

2. Policy Evaluation
   Repeat
   $\Delta \leftarrow 0$
   For each $s \in \mathcal{S}$:
   $\mathrm{v} \leftarrow V(s)$
   $V(s) \leftarrow \Sigma_{a \in \mathcal{A}} \pi(a|s) \left(r(s,a) + \gamma \Sigma_{s' \in \mathcal{S}} T(s'|s,a) V(s')\right)$
   $\Delta \leftarrow \max(\Delta, |\mathrm{v} - V(s)|)$
   until $\Delta < \theta$ (a small positive number)

3. Policy Improvement
   policy-stable $\leftarrow$ *true*
   For each $s \in \mathcal{S}$:
   $a \leftarrow \pi(s)$
   $\pi(s) \leftarrow \arg\max r(s,a) + \gamma \Sigma_{s' \in \mathcal{S}} T(s'|s,a) \mathrm{v}_\pi(s')$
   If $a \neq \pi(s)$, then *policy-stable* $\leftarrow$ *false*
   If *policy-stable*, then stop and return V and π; else go to 2

Iterative Policy Eval for the Small Gridworld

Policy π, an equiprobable random action



$R = -1$
on all transitions

$\gamma = 1$

- An undiscounted episodic task
- Nonterminal states: 1, 2, … , 14
- Terminal state: one, shown in shaded square
- Actions that take the agent off the grid leave the state unchanged
- Reward is -1 until the terminal state is reached

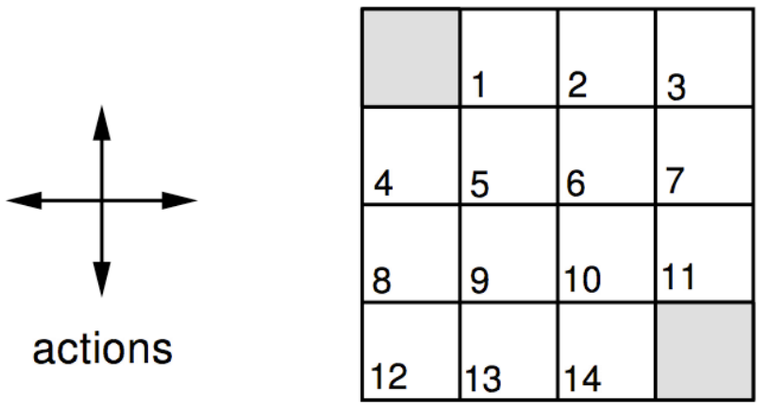
Iterative Policy Eval for the Small Gridworld

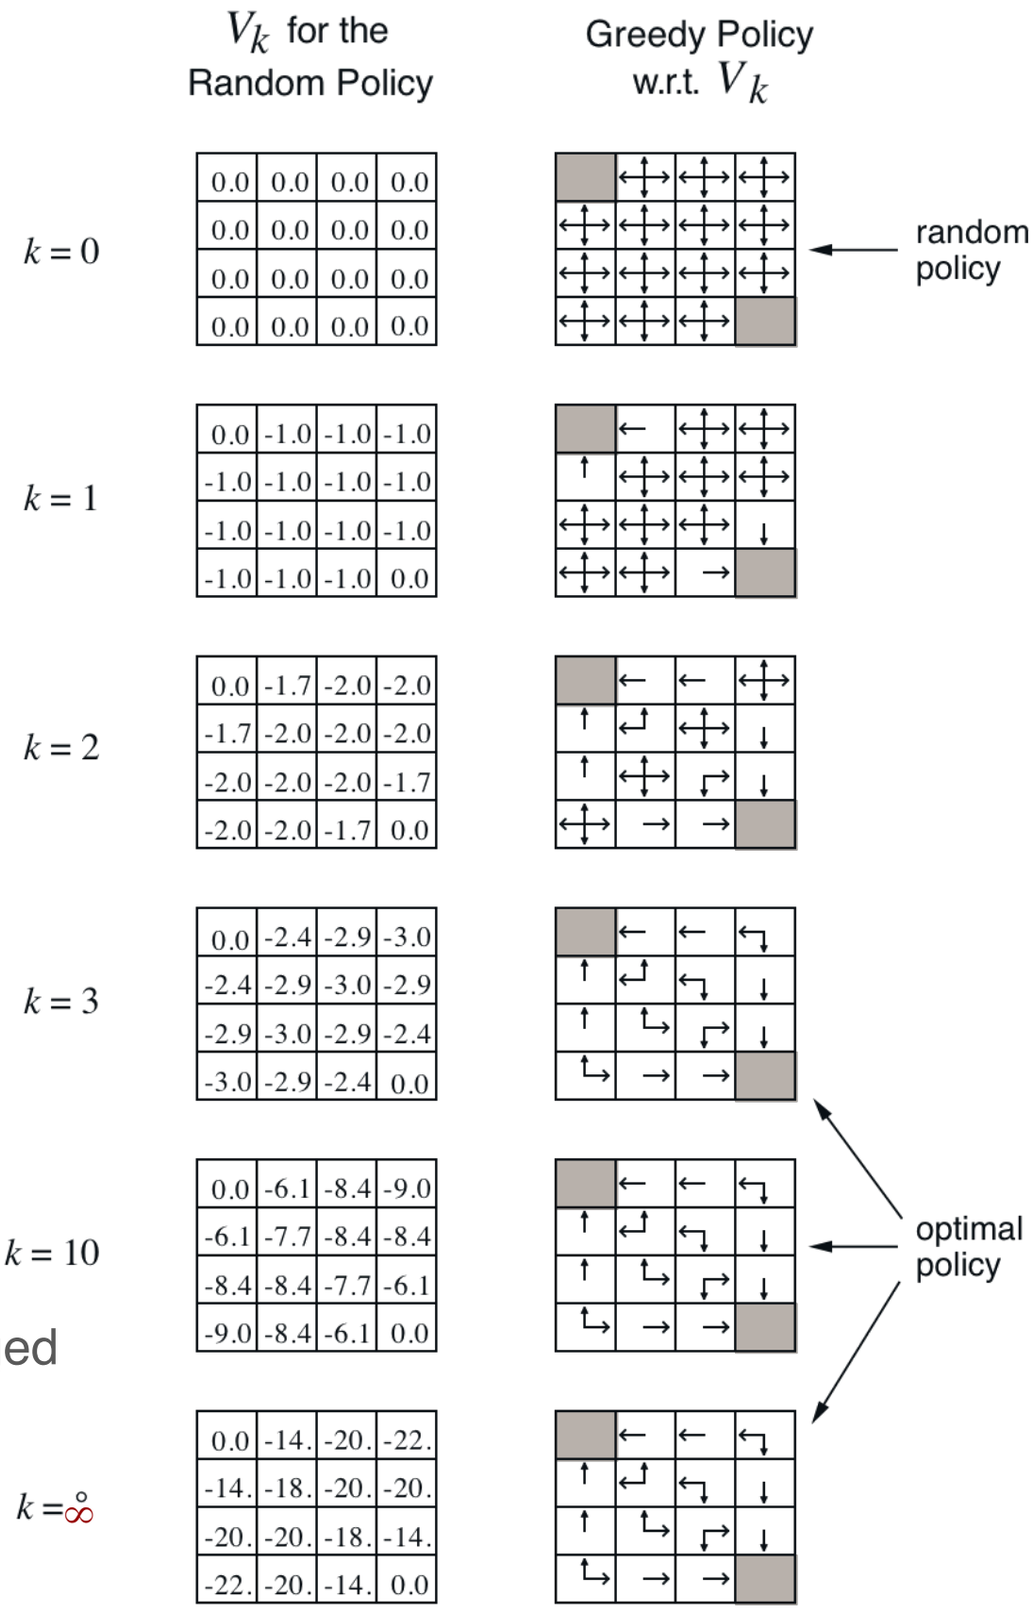
Policy π, an equiprobable random action



$R = -1$
on all transitions

$\gamma = 1$

- An undiscounted episodic task
- Nonterminal states: 1, 2, … , 14
- Terminal state: one, shown in shaded square
- Actions that take the agent off the grid leave the state unchanged
- Reward is -1 until the terminal state is reached

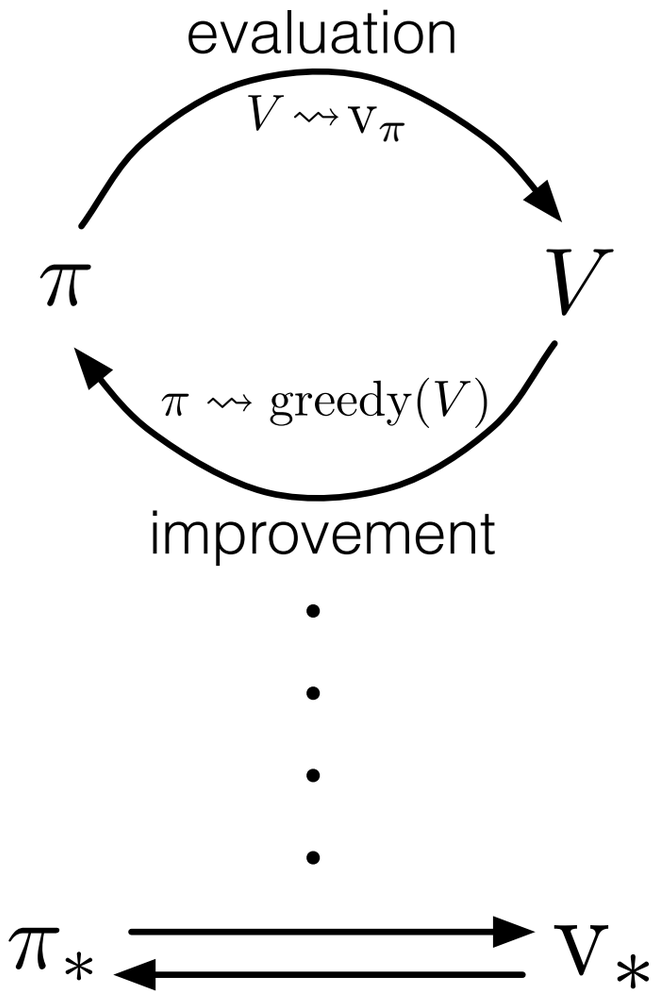


Generalized Policy Iteration

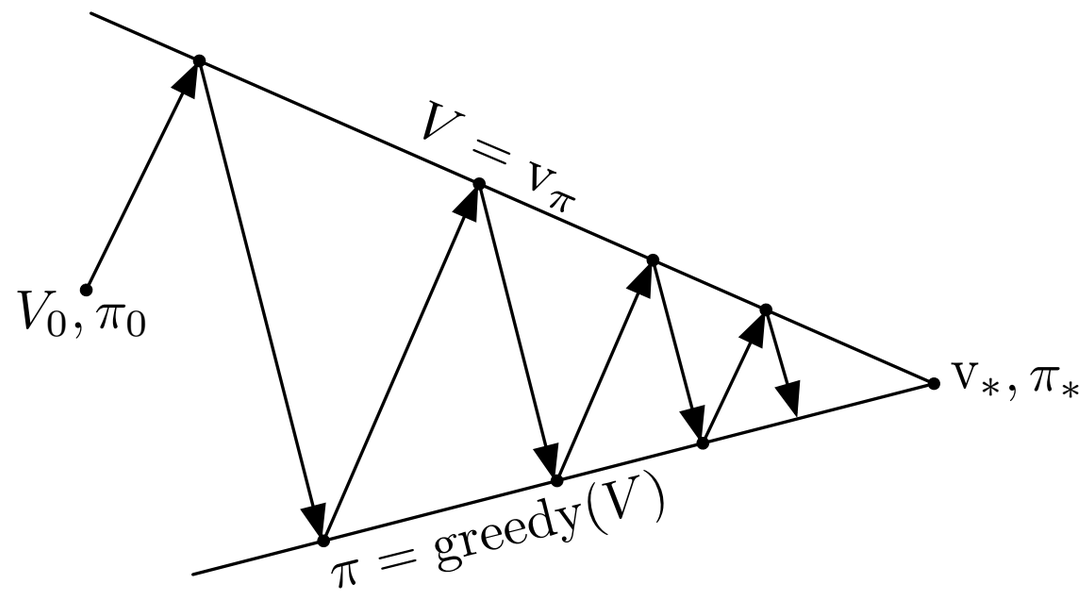
- Does policy evaluation need to converge to v_π?
- Or should we introduce a stopping condition
  - e.g. ϵ-convergence of value function
- Or simply stop after ***k*** iterations of iterative policy evaluation?
- For example, in the small grid world ***k*** = 3 was sufficient to achieve optimal policy
- Why not update policy every iteration? i.e. stop after ***k*** = 1
  - This is equivalent to value iteration (next section)

Generalized Policy Iteration

Generalized Policy Iteration (GPI): any interleaving of policy evaluation and policy improvement, independent of their granularity.



A geometric metaphor for convergence of GPI:



Principle of Optimality

- Any optimal policy can be subdivided into two components:
  - An optimal first action $\mathcal{A}_*$
  - Followed by an optimal policy from successor state $\mathcal{S}'$

- Theorem (Principle of Optimality)
  - A policy $\pi(a|s)$ achieves the optimal value from state s, $\mathrm{v}_\pi(s) = \mathrm{v}_*(s)$, if and only if
  - For any state s' reachable from s, π achieves the optimal value from state s', $\mathrm{v}_\pi(s') = \mathrm{v}_*(s')$

Value Iteration

- If we know the solution to subproblems $\mathrm{v}_*(s')$
- Then solution $\mathrm{v}_*(s')$ can be found by one-step lookahead

$$\mathrm{v}_*(s) \leftarrow \max_{a \in \mathcal{A}} r(s,a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s,a)\mathrm{v}_*(s')$$

- The idea of value iteration is to apply these updates iteratively
- Intuition: start with final rewards and work backwards
- Still works with loopy, stochastic MDPs

Example: Shortest Path

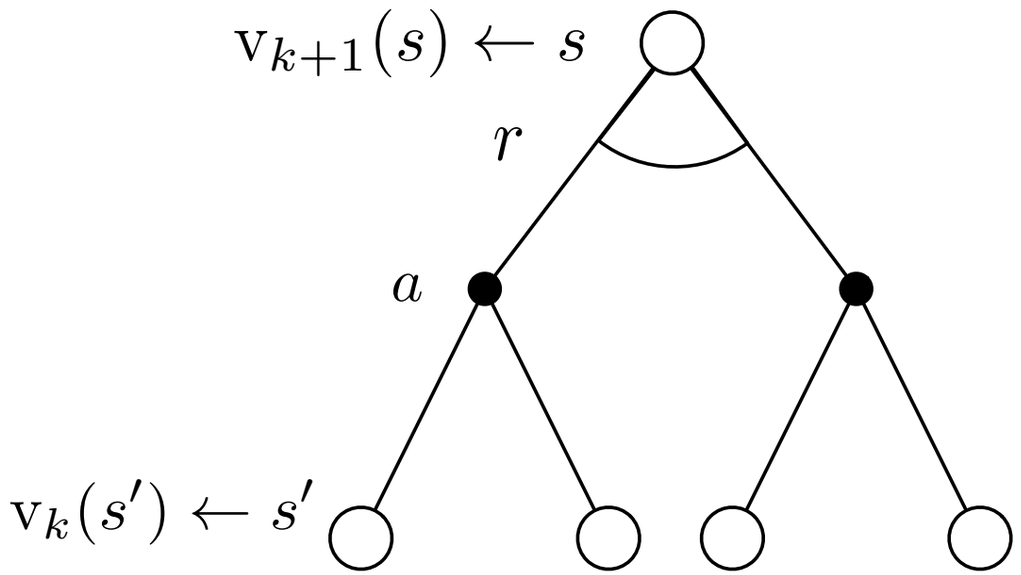
V_7

Value Iteration

- Problem: find optimal policy π
- Solution: iterative application of Bellman optimality backup
- $\mathrm{v}_1 \rightarrow \mathrm{v}_2 \rightarrow \ldots \rightarrow \mathrm{v}_*$
- Using synchronous backups
  - At each iteration ***k*** + 1
  - For all states $s \in \mathcal{S}$
  - Update $\mathrm{v}_{k+1}(s)$ from $\mathrm{v}_k(s')$

Value Iteration (2)



$$\mathrm{v}_{k+1}(s) = \max_{a \in \mathcal{A}} \left(r(s,a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s,a) \mathrm{v}_k(s') \right)$$

$$\mathrm{v}_{k+1} = \max_{a \in \mathcal{A}} r(a) + \gamma T(a) \mathrm{v}_k$$

Bellman Optimality Backup is a Contraction

- Define the Bellman optimality backup operator F^*,

$$F^*(\mathrm{v}) = \max_{a \in \mathcal{A}} r(a) + \gamma T(a)\mathrm{v}$$

- This operator is a γ-contraction, i.e. it makes value functions closer by at least γ (similar to previous proof)

$$||F^*(\mathrm{u}) - F^*(\mathrm{v})||_\infty \leq \gamma ||\mathrm{u} - \mathrm{v}||_\infty$$

Convergence of Value Iteration

- The Bellman optimality operator F^* has a unique fixed point
- v_* is a fixed point of F^* (by Bellman optimality equation)
- By contraction mapping theorem
- Value iteration converges on v_*

Synchronous Dynamic Programming Algorithms

Problem	Bellman Equation	Algorithm
Prediction	Bellman Expectation Equation	Iterative Policy Evaluation
Control	Bellman Expectation Equation + Greedy Policy Improvement	Policy Iteration
Control	Bellman Optimality Equation	Value Iteration

- Algorithms are based on state-value function $\mathrm{v}_\pi(s)$ or $\mathrm{v}_*(s)$
- Complexity $O(mn^2)$ per iteration, for m actions and n states
- Could also apply to action-value function $q_\pi(s,a)$ or $q_*(s,a)$
- Complexity $O(m^2n^2)$ per iteration

Efficiency of DP

- To find an optimal policy is polynomial in the number of states…
- BUT, the number of states is often astronomical, e.g., often growing exponentially with the number of state variables (what Bellman called “the curse of dimensionality”).
- In practice, classical DP can be applied to problems with a few millions of states.

Asynchronous DP

- All the DP methods described so far require exhaustive sweeps of the entire state set.
- Asynchronous DP does not use sweeps. Instead it works like this:
  - Repeat until convergence criterion is met:
    - Pick a state at random and apply the appropriate backup
- Still need lots of computation, but does not get locked into hopelessly long sweeps
- Guaranteed to converge if all states continue to be selected
- Can you select states to backup intelligently? YES: an agent's experience can act as a guide.

Asynchronous Dynamic Programming

- Three simple ideas for asynchronous dynamic programming:
  - In-place dynamic programming
  - Prioritized sweeping
  - Real-time dynamic programming

In-Place Dynamic Programming

- Synchronous value iteration stores two copies of value function
  - for all s in $\mathcal{S}$

$$\mathrm{v}_{new}(s) \leftarrow \max_{a \in \mathcal{A}} \left(r(s,a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s,a) \mathrm{v}_{old}(s') \right)$$

$$\mathrm{v}_{old} \leftarrow \mathrm{v}_{new}$$

- In-place value iteration only stores one copy of value function
  - for all s in $\mathcal{S}$

$$\mathrm{v}(s) \leftarrow \max_{a \in \mathcal{A}} \left(r(s,a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s,a) \mathrm{v}(s') \right)$$

Prioritized Sweeping

- Use magnitude of Bellman error to guide state selection, e.g.

$$\left| \max_{a \in \mathcal{A}} \left(r(s,a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s,a) \mathrm{v}(s') \right) - \mathrm{v}(s) \right|$$

- Backup the state with the largest remaining Bellman error
- Update Bellman poor of affected states after each backup
- Requires knowledge of reverse dynamics (predecessor states)
- Can be implemented efficiently by maintaining a priority queue

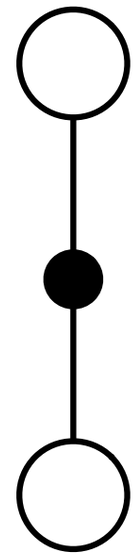
Real-time Dynamic Programming

- Idea: only states that are relevant to agent
- Use agent's experience to guide the selection of states
- After each time-step $\mathcal{S}_t, \mathcal{A}_t, r_{t+1}$
- Backup the state $\mathcal{S}_t$

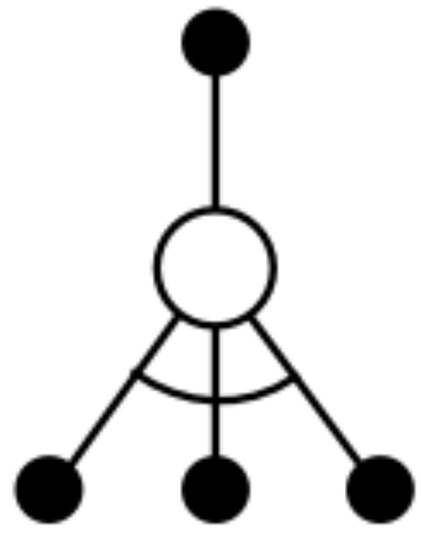
$$\mathrm{v}(\mathcal{S}_t) \leftarrow \max_{a \in \mathcal{A}} \left(r(\mathcal{S}_t, a) + \gamma \sum_{s' \in \mathcal{S}} T(s' | \mathcal{S}_t, a) \mathrm{v}(s') \right)$$

Sample Backups

- In subsequent lectures we will consider sample backups
- Using sample rewards and sample transitions $(\mathcal{S}, \mathcal{A}, r, \mathcal{S}')$
- Instead of reward function and transition dynamics
- Advantages:



- Model-free: no advance knowledge of MDP required
- Breaks the curse of dimensionality through sampling
- Cost of backup is constant, independent of $n = |\mathcal{S}|$



Approximate Dynamic Programming

- Approximate the value function
- Using a function approximate $\hat{\mathrm{v}}(s, \mathrm{w})$
- Apply dynamic programming to $\hat{\mathrm{v}}(\cdot\,, \mathrm{w})$
- e.g. Fitted Value Iteration repeats at each iteration ***k***,
  - Sample states $\tilde{\mathcal{S}} \subseteq \mathcal{S}$
  - For each state $s \in \tilde{\mathcal{S}}$, estimate target value using Bellman optimality equation,

$$\tilde{\mathrm{v}}_k(s) = \max_{a \in \mathcal{A}} \left(r(s,a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s,a) \hat{\mathrm{v}}(s', \mathrm{w}_k) \right)$$

  - Train next value function $\hat{\mathrm{v}}(\cdot\,, \mathrm{w}_{k+1})$ using targets $\{\langle s, \tilde{\mathrm{v}}_k(s) \rangle\}$

Linear Programming (LP)

- Recall, at value iteration convergence we have

$$\forall s \in \mathcal{S}: \quad V^*(s) = \max_{a \in \mathcal{A}} \left(r(s,a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s,a) V^*(s') \right)$$

- LP formulation to find

$$\min_V \quad \sum_{\mathcal{S}} \mu_0(s) V(s)$$

$$\text{s.t.} \quad \forall s \in \mathcal{S}, \forall a \in \mathcal{A}:$$

$$V(s) \geq r(s,a) + \gamma \sum_{s' \in \mathcal{S}} T(s'|s,a) V^*(s')$$

μ_0 is a probability distribution over $\mathcal{S}$, with $\mu_0(s) > 0$ for all s in $\mathcal{S}$.

Theorem. V^* is the solution to the above LP.

LP con't

- Let F be the Bellman operator, i.e., $V_{i+1}^* = F(V_i)$. Then the LP can be written as:

$$\min_V \quad \mu_0^\top V$$
$$\text{s.t.} \quad V \geq F(V)$$

Monotonicity Property: If $U \geq V$ then $F(U) \geq F(V)$.
Hence, if $V \geq F(V)$ then $F(V) \geq F(F(V))$, and by repeated application, $V \geq F(V) \geq F^2V \geq F^3V \geq ... \geq F^\infty V = V^*$
Any feasible solution to the LP must satisfy $V \geq F(V)$, and hence must satisfy $V \geq V^*$. Hence, assuming all entries in μ_0 are positive, V^* is the optimal solution to the LP.

LP: The Dual -> q*

$$\min_{\lambda} \quad \sum_{s\in\mathcal{S}}\sum_{a\in\mathcal{A}}\sum_{s'\in\mathcal{S}} \lambda(s,a)T(s,a,s')r(s,a)$$

$$\text{s.t.} \quad \forall s \in \mathcal{S} : \sum_{a'\in\mathcal{A}} \lambda(s',a') = \mu_0(s) + \gamma \sum_{s\in\mathcal{S}}\sum_{a\in\mathcal{A}} \lambda(s,a)T(s,a,s')$$

- Interpretation
  - $\lambda(s,a) = \sum_{t=0}^{\infty} \gamma^t P(s_t = s, a_t = a)$
  - Equation 2: ensures that λ has the above meaning
  - Equation 1: maximize expected discounted sum of rewards
- Optimal policy: $\pi^*(s) = \arg\max_a \lambda(s,a)$
