Canonical Machine Learning Problems

- Linear Classification
- Polynomial Regression
- Clustering with Gaussian Mixtures

Linear Classification

- **Data**: $\mathcal{D} = \{(\mathbf{x}_i, y_i)\}_{i=1}^n$.

  $\mathbf{x}_i \in \mathbb{R}^D$

  $y_i \in \{+1, -1\}$.

  - **Model**:

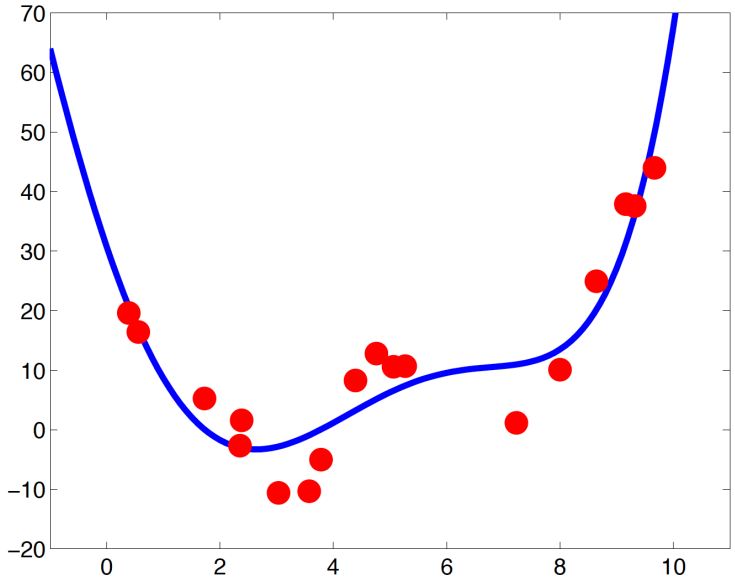
$$p(y_i = +1|\boldsymbol{\theta}, \mathbf{x}) = \begin{cases} 1 \text{ if } \boldsymbol{\theta}^{\mathrm{T}}\mathbf{x}_i \geq 0, \\ 0 \quad \text{otherwise} \end{cases} \tag{1}$$

  - **Parameters**: $\boldsymbol{\theta} \in \mathbb{R}^D$
  - **Goal**: To infer $\boldsymbol{\theta}$ from data and to predict future labels $p(y|\mathcal{D}, \mathbf{x})$.

Polynomial Regression

- **Data**: $\mathcal{D} = \{(\mathbf{x}_i, y_i)\}_{i=1}^n$.

$$\mathbf{x}_i \in \mathbb{R}$$
$$y_i \in \mathbb{R}\,.$$



- **Model**: $y_i = a_0 + a_1 x_i + a_2 x_i^2 + \cdots + a_m x_i^m + \epsilon_i$,
  where $\epsilon_i \sim \mathcal{N}(0, \sigma^2)$.
- **Parameters**: $\boldsymbol{\theta} = (a_0, \ldots, a_m, \sigma^2)^{\mathrm{T}}$.
- **Goal**: To infer $\boldsymbol{\theta}$ from the data and to predict future outputs $p(y|\mathcal{D}, x, m)$.

Clustering with Gaussian Mixtures (Density Estimation)

- **Data**: $\mathcal{D} = \{\mathbf{x}_i\}_{i=1}^n$

  $\mathbf{x}_i \in \mathbb{R}^D$

  - **Model**:

$$\mathbf{x}_i \sim \sum_{j=1}^{m} w_j p_j(\mathbf{x}_i) \tag{2}$$

$$\text{where } p_j(\mathbf{x}_i) = \mathcal{N}(\mathbf{x}_i; \boldsymbol{\mu}_i, \Sigma_i)\,. \tag{3}$$

  - **Parameters**: $\boldsymbol{\theta} = ((\boldsymbol{\mu}_1, \Sigma_1), \ldots, (\boldsymbol{\mu}_m, \Sigma_m), \mathbf{w})$
  - **Goal**: To infer $\boldsymbol{\theta}$ from the data, predict the density $p(\mathbf{x}|\mathcal{D}, m)$, and infer which points belong to which cluster.

Bayesian Modelling (Theory of Everything)

Everything follows from two simple rules:

Sum rule: $P(x) = \sum_y P(x, y)$

Product rule: $P(x, y) = P(x)P(y|x)$

$$P(\theta|\mathcal{D}, m) = \frac{P(\mathcal{D}|\theta, m)P(\theta|m)}{P(\mathcal{D}|m)}$$

$P(\mathcal{D}\|\theta, m)$	likelihood of parameters θ in model m
$P(\theta\|m)$	prior probability of θ
$P(\theta\|\mathcal{D}, m)$	posterior of θ given data $\mathcal{D}$

Prediction:

$$P(x|\mathcal{D}, m) = \int P(x|\theta, \mathcal{D}, m)P(\theta|\mathcal{D}, m)d\theta$$

Model Comparison:

$$P(m|\mathcal{D}) = \frac{P(\mathcal{D}|m)P(m)}{P(\mathcal{D})}$$

$$P(\mathcal{D}|m) = \int P(\mathcal{D}|\theta, m)P(\theta|m)\, d\theta$$

Ghahramani (2015)

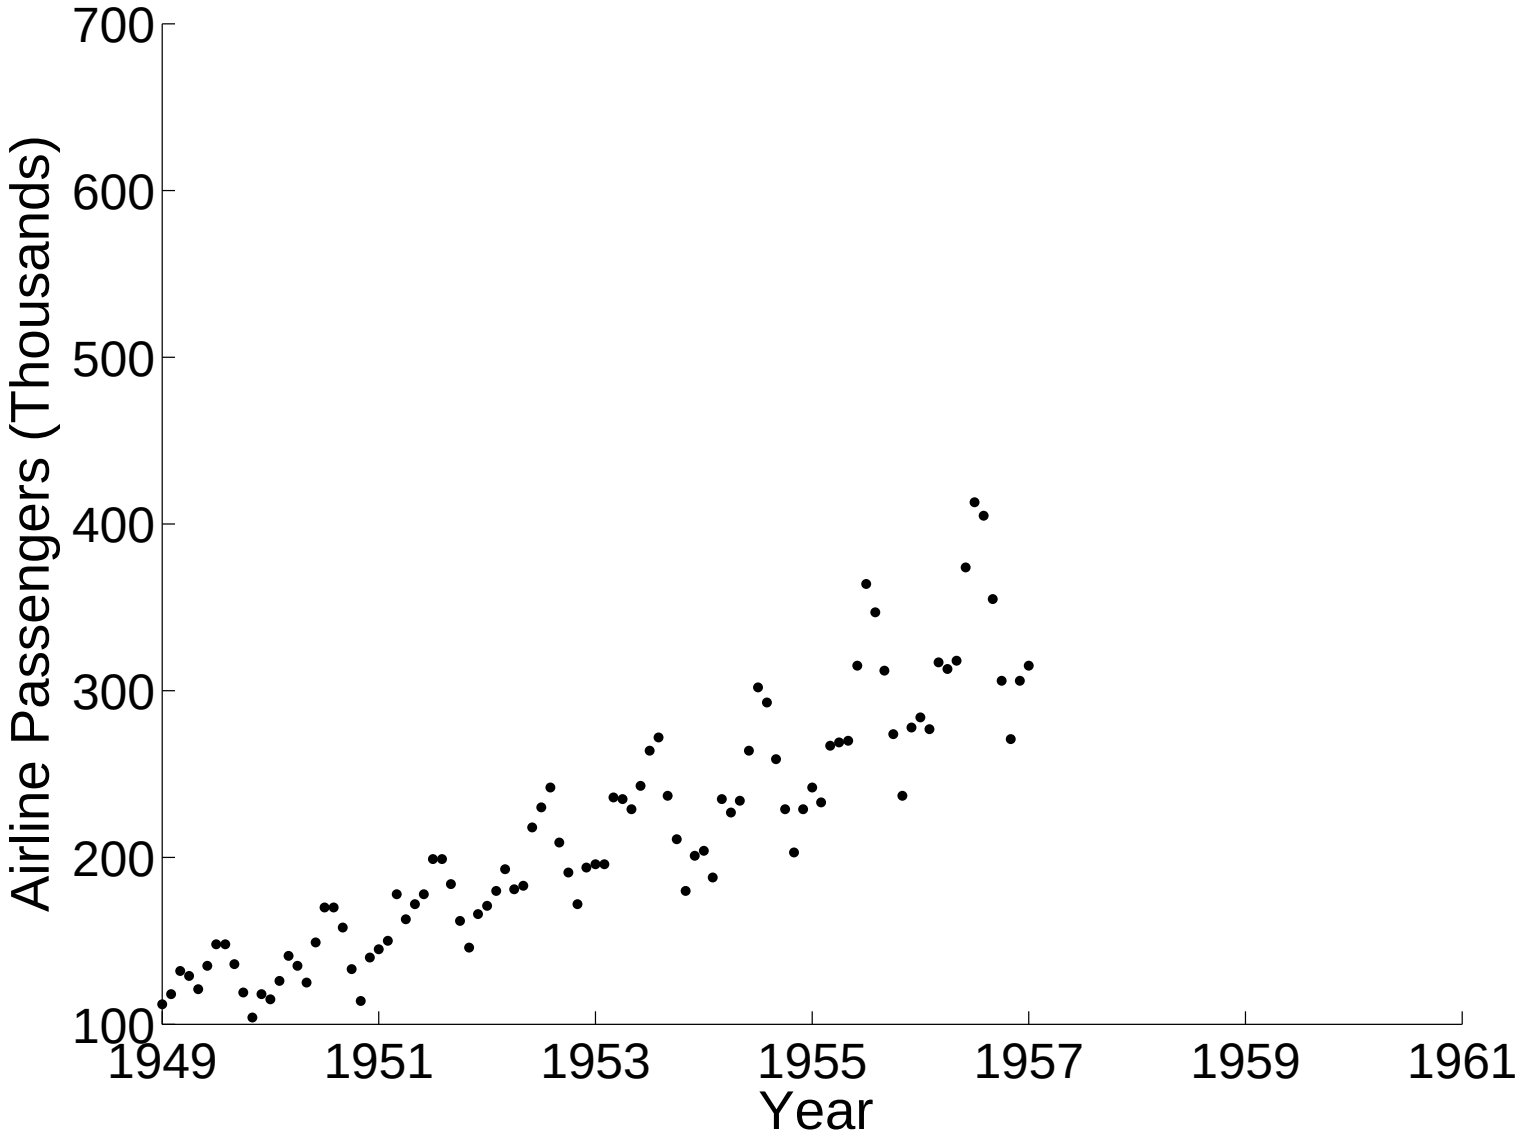
Basic Regression Problem

- Training set of N targets (observations) $\mathbf{y} = (y(x_1), \ldots, y(x_N))^{\mathrm{T}}$.
- Observations evaluated at inputs $X = (x_1, \ldots, x_N)^{\mathrm{T}}$.
- Want to predict the value of $y(x_*)$ at a test input x_*.

For example: Given CO_2 concentrations $\mathbf{y}$ measured at times X, what will the CO_2 concentration be for $x_* = 2024$, 10 years from now?

Just knowing high school math, what might you try?

Statistics from Scratch



Guess the parametric form of a function that could fit the data

- $f(x, \mathbf{w}) = \mathbf{w}^{\mathrm{T}} x$ [Linear function of $\mathbf{w}$ and x]
- $f(x, \mathbf{w}) = \mathbf{w}^{\mathrm{T}} \boldsymbol{\phi}(x)$ [Linear function of $\mathbf{w}$] (Linear Basis Function Model)
- $f(x, \mathbf{w}) = g(\mathbf{w}^{\mathrm{T}} \boldsymbol{\phi}(x))$ [Non-linear in x and $\mathbf{w}$] (E.g., Neural Network)

$\boldsymbol{\phi}(x)$ is a vector of basis functions. For example, if $\boldsymbol{\phi}(x) = (1, x, x^2)$ and $x \in \mathbb{R}^1$ then $f(x, \mathbf{w}) = w_0 + w_1 x + w_2 x^2$ is a quadratic function.

Choose an error measure $E(\mathbf{w})$, minimize with respect to $\mathbf{w}$

- $E(\mathbf{w}) = \sum_{i=1}^{N} [f(x_i, \mathbf{w}) - y(x_i)]^2$

A probabilistic approach

We could explicitly account for noise in our model.

- $y(x) = f(x, \mathbf{w}) + \epsilon(x)$, where $\epsilon(x)$ is a noise function.

One commonly takes $\epsilon(x) = \mathcal{N}(0, \sigma^2)$ for i.i.d. additive Gaussian noise, in which case

$$p(y(x)|x, \mathbf{w}, \sigma^2) = \mathcal{N}(y(x); f(x, \mathbf{w}), \sigma^2) \qquad \text{Observation Model} \qquad (4)$$

$$p(\mathbf{y}|x, \mathbf{w}, \sigma^2) = \prod_{i=1}^{N} \mathcal{N}(y(x_i); f(x_i, \mathbf{w}), \sigma^2) \qquad \text{Likelihood} \qquad (5)$$

- Maximize the likelihood of the data $p(\mathbf{y}|x, \mathbf{w}, \sigma^2)$ with respect to $\sigma^2, \mathbf{w}$.

For a Gaussian noise model, this approach will make the same predictions as using a squared loss error function:

$$\log p(\mathbf{y}|X, \mathbf{w}, \sigma^2) \propto -\frac{1}{2\sigma^2} \sum_{i=1}^{N} [f(x_i, \mathbf{w}) - y(x_i)]^2 \qquad (6)$$

- The probabilistic approach helps us interpret the error measure in a deterministic approach, and gives us a sense of the noise level σ^2.
- Probabilistic methods thus provide an intuitive framework for representing uncertainty, and model development.
- Both approaches are prone to *over-fitting* for flexible $f(x, \mathbf{w})$: low error on the training data, high error on the test set.

Regularization

- Use a penalized log likelihood (or error function), such as

$$\log p(\mathbf{y}|X, \mathbf{w}) \propto \overbrace{-\frac{1}{2\sigma^2}\sum_{i=1}^{n}(f(x_i, \mathbf{w}) - y(x_i)^2)}^{\text{model fit}} \overbrace{-\lambda \mathbf{w}^{\mathrm{T}}\mathbf{w}}^{\text{complexity penalty}} \quad . \tag{7}$$

- **But how should we define complexity, and how much should we penalize complexity?**
- Can set λ using *cross-validation*.

Bayesian Inference

Bayes' Rule

$$p(a|b) = p(b|a)p(a)/p(b)\,, \qquad p(a|b) \propto p(b|a)p(a)\,. \tag{8}$$

$$\text{posterior} = \frac{\text{likelihood} \times \text{prior}}{\text{marginal likelihood}}, \quad p(\mathbf{w}|\mathbf{y}, X, \sigma^2) = \frac{p(\mathbf{y}|X, \mathbf{w}, \sigma^2)p(\mathbf{w})}{p(\mathbf{y}|X, \sigma^2)}\,. \tag{9}$$

Predictive Distribution

$$p(y|x_*, \mathbf{y}, X) = \int p(y|x_*, \mathbf{w})p(\mathbf{w}|\mathbf{y}, X)d\mathbf{w}\,. \tag{10}$$

- Think of each setting of $\mathbf{w}$ as a different model. Eq. (15) is a *Bayesian model average*, an average of infinitely many models weighted by their posterior probabilities.
- No over-fitting, automatically calibrated complexity.
- Eq. (10) is intractable for many likelihoods $p(\mathbf{y}|X, \mathbf{w}, \sigma^2)$ and priors $p(\mathbf{w})$.
- Typically more interested in the induced distribution over functions than in parameters $\mathbf{w}$. Can be hard to have intuitions for priors on $p(\mathbf{w})$.

Parametric Regression Review

Deterministic

$$E(\mathbf{w}) = \sum_{i=1}^{N} (f(x_i, \mathbf{w}) - y_i)^2 \,. \tag{11}$$

Maximum Likelihood

$$p(y(x)|x, \mathbf{w}) = \mathcal{N}(y(x); f(x, \mathbf{w}), \sigma_n^2) \,, \tag{12}$$

$$p(\mathbf{y}|X, \mathbf{w}) = \prod_{i=1}^{N} \mathcal{N}(y(x_i); f(x_i, \mathbf{w}), \sigma_n^2) \,. \tag{13}$$

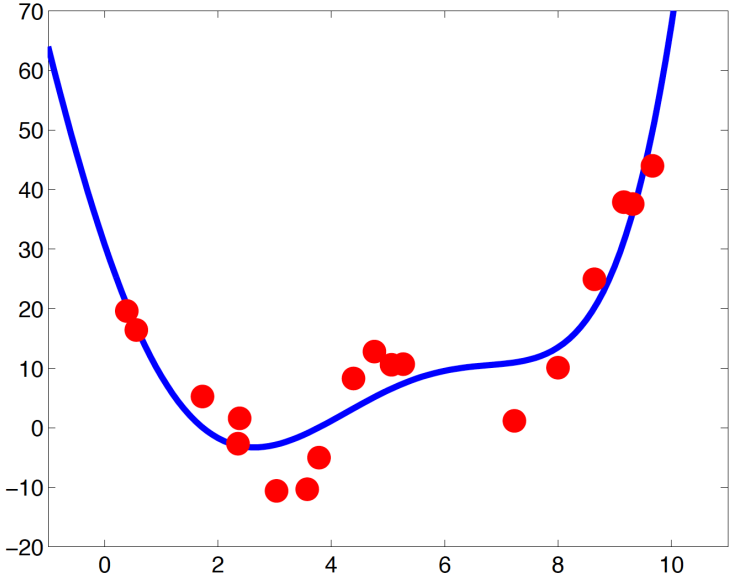
Bayesian

$$\text{posterior} = \frac{\text{likelihood} \times \text{prior}}{\text{marginal likelihood}}, \quad p(\mathbf{w}|\mathbf{y}, X) = \frac{p(\mathbf{y}|X, \mathbf{w})p(\mathbf{w})}{p(\mathbf{y}|X)} \,. \tag{14}$$

$$p(y|x_*, \mathbf{y}, X) = \int p(y|x_*, \mathbf{w})p(\mathbf{w}|\mathbf{y}, X)d\mathbf{w} \,. \tag{15}$$

Worked Example: Basis Regression (Chalkboard)

- We have data $\mathcal{D} = \{(\mathbf{x}_i, y_i)\}_{i=1}^N$



- We use the model:

$$y = \mathbf{w}^{\mathrm{T}} \boldsymbol{\phi}(\mathbf{x}) + \epsilon \tag{16}$$

$$\epsilon \sim \mathcal{N}(0, \sigma^2)\,. \tag{17}$$

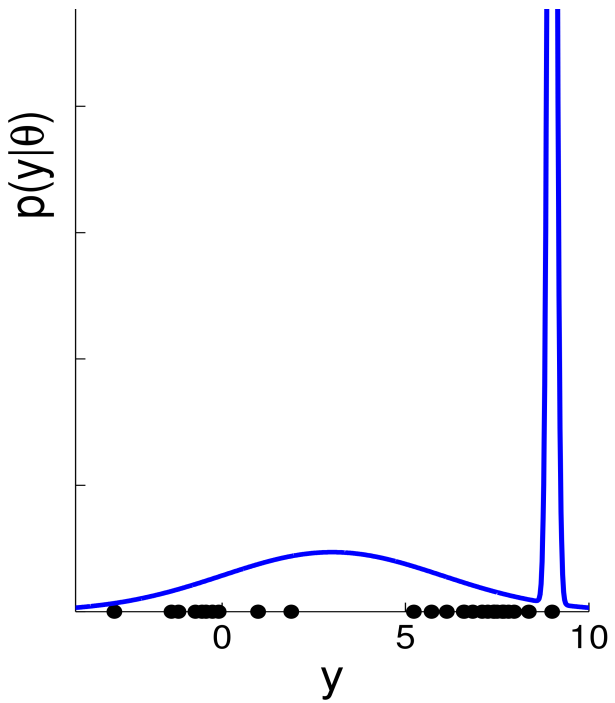
- We want to make predictions of y_* for any $\mathbf{x}_*$.
- We will now explore this question on the whiteboard using maximum likelihood and Bayesian approaches.
- We will consider topics such as *regularization*, *cross-validation*, *Bayesian model averaging* and *conjugate priors*.

Rant: Regularisation = MAP $\neq$ Bayesian Inference

Example: Density Estimation

- Observations $y_1, \ldots, y_N$ drawn from unknown density $p(y)$.
- Model $p(y|\theta) = w_1 \mathcal{N}(y|\mu_1, \sigma_1^2) + w_2 \mathcal{N}(y|\mu_2, \sigma_2^2)$,
  $\theta = \{w_1, w_2, \mu_1, \mu_2, \sigma_1, \sigma_2\}$.
- Likelihood $p(\mathbf{y}|\theta) = \prod_{i=1}^{N} p(y_i|\theta)$.

Can learn all free parameters θ using maximum likelihood...



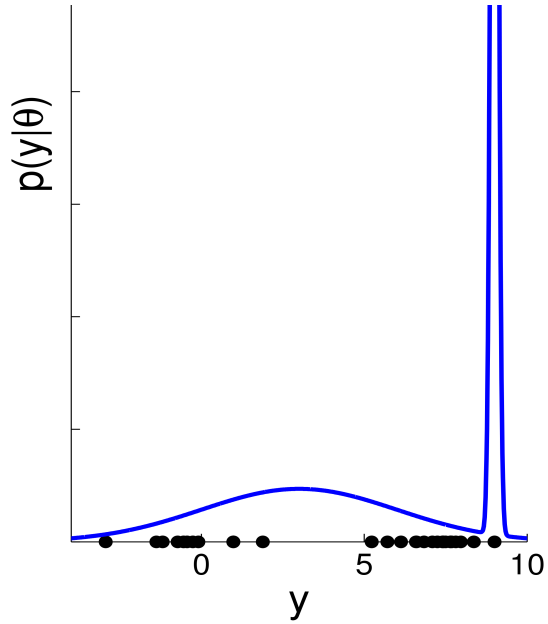
Regularisation = MAP $\neq$ Bayesian Inference

Regularisation or MAP

- Find

$$\text{argmax}_\theta \log p(\theta|\mathbf{y}) \stackrel{c}{=} \overbrace{\log p(\mathbf{y}|\theta)}^{\text{model fit}} + \overbrace{\log p(\theta)}^{\text{complexity penalty}}$$

- Choose $p(\theta)$ such that $p(\theta) \to 0$ faster than $p(\mathbf{y}|\theta) \to \infty$ as σ_1 or $\sigma_2 \to 0$.



Bayesian Inference

- Predictive Distribution: $p(y_*|\mathbf{y}) = \int p(y_*|\theta)p(\theta|\mathbf{y})d\theta$.
- Parameter Posterior: $p(\theta|\mathbf{y}) \propto p(\mathbf{y}|\theta)p(\theta)$.
- $p(\theta)$ need not be zero anywhere in order to make reasonable inferences. Can use a sampling scheme, with conjugate posterior updates for each separate mixture component, using an inverse Gamma prior on the variances σ_1^2, σ_2^2.

Learning with Stochastic Gradient Descent

Chalkboard.
