Outline

Generative vs. Discriminative Classifiers

- Probabilistic classification task:

$$p(Y = \mathit{benign}|\mathbf{X} = \mathbf{x}), p(Y = \mathit{malicious}|\mathbf{X} = \mathbf{x})$$

- How do you estimate $p(y|\mathbf{x})$?

$$p(y|\mathbf{x}) = \frac{p(y, \mathbf{x})}{p(\mathbf{x})} = \frac{p(\mathbf{x}|y)p(y)}{p(\mathbf{x})}$$

- Two step approach - Estimate generative model and then posterior for y (Naïve Bayes)
- Solving a more general problem [2, 1]
- Why not directly model $p(y|\mathbf{x})$? - **Discriminative approach**

Which is Better?

- Number of training examples needed to learn a PAC-learnable classifier $\propto$ *VC-dimension of the hypothesis space*
- VC-dimension of a probabilistic classifier $\propto$ Number of parameters [2] (or a small polynomial in the number of parameters)
- Number of parameters for $p(y, \mathbf{x}) >$ Number of parameters for $p(y|\mathbf{x})$

Discriminative classifiers need lesser training examples to for PAC learning than generative classifiers

Logistic Regression

- $y|\mathbf{x}$ is a *Bernoulli* distribution with parameter $\theta = sigmoid(\mathbf{w}^\top \mathbf{x})$
- When a new input $\mathbf{x}^*$ arrives, we toss a coin which has $sigmoid(\mathbf{w}^\top \mathbf{x}^*)$ as the probability of heads
- If outcome is heads, the predicted class is 1 else 0
- Learns a linear boundary

Learning Task for Logistic Regression

Given training examples $\langle \mathbf{x}_i, y_i \rangle_{i=1}^{D}$, learn $\mathbf{w}$

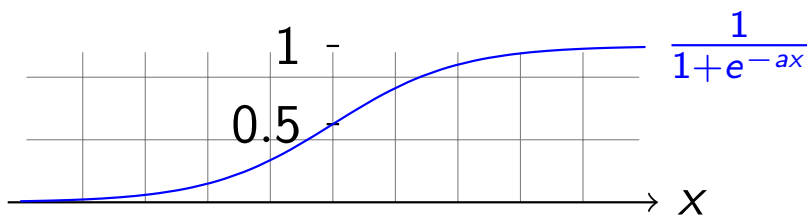
Logistic Regression - Recap

Bayesian Interpretation

- Directly model $p(y|\mathbf{x})$ $(y \in \{0, 1\})$
- $p(y|\mathbf{x}) \sim Bernoulli(\theta = sigmoid(\mathbf{w}^\top \mathbf{x}))$

Geometric Interpretation

- Use regression to predict discrete values
- *Squash* output to $[0, 1]$ using sigmoid function
- Output less than 0.5 is one class and greater than 0.5 is the other



Learning Parameters

- MLE Approach
- Assume that $y \in \{0, 1\}$
- What is the likelihood for a bernoulli sample?
  - If $y_i = 1$, $p(y_i) = \theta_i = \frac{1}{1+exp(-\mathbf{w}^\top \mathbf{x}_i)}$
  - If $y_i = 0$, $p(y_i) = 1 - \theta_i = \frac{1}{1+exp(\mathbf{w}^\top \mathbf{x}_i)}$
  - In general, $p(y_i) = \theta_i^{y_i}(1-\theta_i)^{1-y_i}$

Log-likelihood

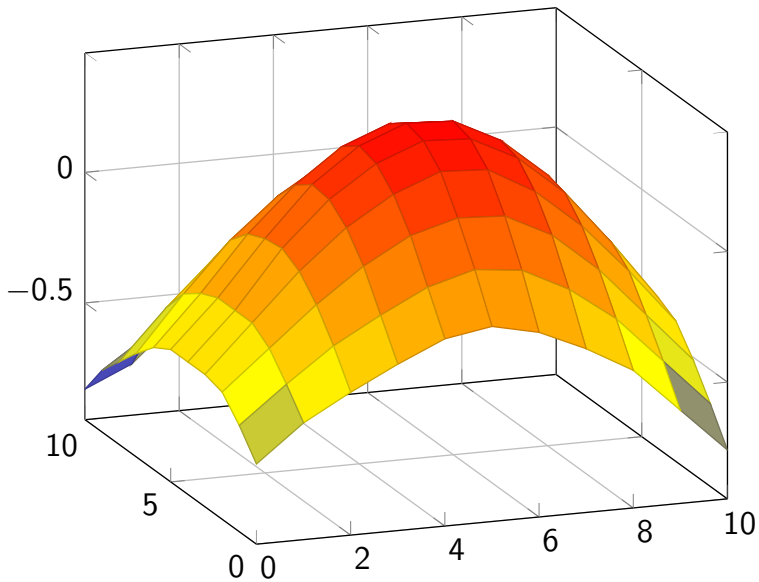
$$LL(\mathbf{w}) = \sum_{i=1}^{N} y_i \log \theta_i + (1 - y_i) \log (1 - \theta_i)$$

- No closed form solution for maximizing log-likelihood

Using Gradient Descent for Learning Weights

- Compute gradient of LL with respect to $\mathbf{w}$
- A convex function of $\mathbf{w}$ with a unique global maximum

$$\frac{d}{d\mathbf{w}} LL(\mathbf{w}) = \sum_{i=1}^{N} (y_i - \theta_i)\mathbf{x}_i$$



- Update rule:

$$\mathbf{w}_{k+1} = \mathbf{w}_k + \eta \frac{d}{d\mathbf{w}_k} LL(\mathbf{w}_k)$$

Using Newton's Method

- Setting η is sometimes *tricky*
- Too large – incorrect results
- Too small – slow convergence
- Another way to speed up convergence:

Newton's Method

$$\mathbf{w}_{k+1} = \mathbf{w}_k + \eta \mathbf{H}_k^{-1} \frac{d}{d\mathbf{w}_k} LL(\mathbf{w}_k)$$

What is the Hessian?

- Hessian or **H** is the second order derivative of the objective function
- Newton's method belong to the family of **second order optimization algorithms**
- For logistic regression, the Hessian is:

$$H = -\sum_i \theta_i(1-\theta_i)\mathbf{x}_i\mathbf{x}_i^\top$$

Regularization with Logistic Regression

- **Overfitting** is an issue, especially with large number of features
- Add a *Gaussian prior* $\sim \mathcal{N}(\mathbf{0}, \tau^2)$ (Or a regularization penalty)
- Easy to incorporate in the gradient descent based approach

$$LL'(\mathbf{w}) = LL(\mathbf{w}) - \frac{1}{2}\lambda \mathbf{w}^\top \mathbf{w}$$

$$\frac{d}{d\mathbf{w}} LL'(\mathbf{w}) = \frac{d}{d\mathbf{w}} LL(\mathbf{w}) - \lambda \mathbf{w}$$

$$H' = H - \lambda I$$

where I is the identity matrix.

Handling Multiple Classes

- One vs. Rest and One vs. Other
- $p(y|\mathbf{x}) \sim Multinoulli(\boldsymbol{\theta})$
- Multinoulli parameter vector $\boldsymbol{\theta}$ is defined as:

$$\theta_j = \frac{exp(\mathbf{w}_j^\top \mathbf{x})}{\sum_{k=1}^{C} exp(\mathbf{w}_k^\top \mathbf{x})}$$

- Multiclass logistic regression has C weight vectors to learn

Bayesian Logistic Regression

- How to get the posterior for $\mathbf{w}$?
- Not easy - *Why?*

Laplace Approximation

- We do not know what the true posterior distribution for $\mathbf{w}$ is.
- Is there a close-enough (approximate) Gaussian distribution?

Laplace Approximation

Problem Statement

How to approximate a posterior with a Gaussian distribution?

- When is this needed?
  - When direct computation of posterior is not possible.
  - No conjugate prior ☹

Laplace Approximation using Taylor Series Expansion

Laplace Approximation using Taylor Series Expansion

- Assume that posterior is:

$$p(\mathbf{w}|D) = \frac{1}{Z} e^{-E(\mathbf{w})}$$

$E(\mathbf{w})$ is **energy function** $\equiv$ negative log of unnormalized log posterior

Laplace Approximation using Taylor Series Expansion

- Assume that posterior is:

$$p(\mathbf{w}|D) = \frac{1}{Z} e^{-E(\mathbf{w})}$$

  $E(\mathbf{w})$ is **energy function** $\equiv$ negative log of unnormalized log posterior

- Let $\mathbf{w}_{MAP}$ be the *mode* or *expected value* of the posterior distribution of $\mathbf{w}$

Laplace Approximation using Taylor Series Expansion

- Assume that posterior is:

$$p(\mathbf{w}|D) = \frac{1}{Z} e^{-E(\mathbf{w})}$$

  $E(\mathbf{w})$ is **energy function** $\equiv$ negative log of unnormalized log posterior

- Let $\mathbf{w}_{MAP}$ be the *mode* or *expected value* of the posterior distribution of $\mathbf{w}$
- Taylor series expansion of $E(\mathbf{w})$ around the mode

$$\begin{aligned} E(\mathbf{w}) &= E(\mathbf{w}_{MAP}) + (\mathbf{w} - \mathbf{w}^*)^\top E'(\mathbf{w}) + (\mathbf{w} - \mathbf{w}^*)^\top E''(\mathbf{w})(\mathbf{w} - \mathbf{w}^*) + . \\ &\approx E(\mathbf{w}_{MAP}) + (\mathbf{w} - \mathbf{w}^*)^\top E'(\mathbf{w}) + (\mathbf{w} - \mathbf{w}_{MAP})^\top E''(\mathbf{w})(\mathbf{w} - \mathbf{w}^*) \end{aligned}$$

  $E'(\mathbf{w}) = \nabla$ - first derivative of $E(\mathbf{w})$ (**gradient**) and $E''(\mathbf{w}) = \mathbf{H}$ is the second derivative (**Hessian**)

Taylor Series Expansion Continued

- Since $\mathbf{w}_{MAP}$ is the mode, the first derivative or gradient is zero

$$E(\mathbf{w}) \approx E(\mathbf{w}_{MAP}) + (\mathbf{w} - \mathbf{w}^*)^\top \mathbf{H} (\mathbf{w} - \mathbf{w}^*)$$

Taylor Series Expansion Continued

- Since $\mathbf{w}_{MAP}$ is the mode, the first derivative or gradient is zero

$$E(\mathbf{w}) \approx E(\mathbf{w}_{MAP}) + (\mathbf{w} - \mathbf{w}^*)^\top \mathbf{H}(\mathbf{w} - \mathbf{w}^*)$$

- Posterior $p(\mathbf{w}|D)$ may be written as:

$$\begin{aligned} p(\mathbf{w}|D) &\approx \frac{1}{Z} e^{-E(\mathbf{w}_{MAP})} exp\left[-\frac{1}{2}(\mathbf{w} - \mathbf{w}^*)^\top \mathbf{H}(\mathbf{w} - \mathbf{w}^*)\right] \\ &= \mathcal{N}(\mathbf{w}_{MAP}, \mathbf{H}^{-1}) \end{aligned}$$

$\mathbf{w}_{MAP}$ is the mode obtained by maximizing the posterior using gradient ascent

Posterior of $\mathbf{w}$ for Logistic Regression

- Prior:

$$p(\mathbf{w}) = \mathcal{N}(\mathbf{0}, \tau^2 \mathbf{I})$$

- Likelihood of data

$$p(D|\mathbf{w}) = \prod_{i=1}^{N} \theta_i^{y_i} (1-\theta_i)^{1-y_i}$$

where $\theta_i = \frac{1}{1+e^{-\mathbf{w}^\top \mathbf{x_i}}}$

- Posterior:

$$p(\mathbf{w}|D) = \frac{\mathcal{N}(\mathbf{0}, \tau^2 \mathbf{I}) \prod_{i=1}^{N} \theta_i^{y_i} (1-\theta_i)^{1-y_i}}{\int p(D|\mathbf{w}) d\mathbf{w}}$$

Approximating the Posterior - Laplace Approximation

- Approximate posterior distribution

$$p(\mathbf{w}|D) = \mathcal{N}(\mathbf{w}_{MAP}, \mathbf{H}^{-1})$$

- $\mathbf{H}$ is the *Hessian* of the negative log-posterior w.r.t. $\mathbf{w}$

Getting Prediction

$$p(y|\mathbf{x}) = \int p(y|\mathbf{x}, \mathbf{w}) p(\mathbf{w}|D) d\mathbf{w}$$

1. Use a point estimate of $\mathbf{w}$ (MLE or MAP)
2. Analytical Result
3. **Monte Carlo Approximation**
   - Numerical integration
   - Sample finite "versions" of $\mathbf{w}$ using $p(\mathbf{w}|D)$

$$p(\mathbf{w}|D) = \mathcal{N}(\mathbf{w}_{MAP}, \mathbf{H}^{-1})$$

   - Compute $p(y|\mathbf{x})$ using the samples and add
