Graphical Models

Lecture 17:

Learning in Undirected Graphical Models

Andrew McCallum
mccallum@cs.umass.edu

Thanks to Noah Smith and Carlos Guestrin for some slide materials.

Learning

- learning input:
  - Graphical model with unknown parameters
  - Observations of variables (training data)
- learning output:
  - Parameters
- Maximum likelihood estimation (MLE):
  - Choose parameters that give highest probability to observed training data

Parameter Estimation in Bayesian Networks: Decomposability

$$
\begin{aligned}
\boldsymbol{\theta}_{\mathrm{MLE}} &= \arg\max_{\theta} \prod_{t} P(\boldsymbol{X} = \boldsymbol{x}^{(t)} \mid \boldsymbol{\theta}) \\
&= \arg\max_{\boldsymbol{\theta}} \prod_{t} \prod_{i} P(X_i = x_i^{(t)} \mid \mathrm{Parents}(X_i) = \mathrm{Parents}(x_i), \boldsymbol{\theta}) \\
&= \arg\max_{\boldsymbol{\theta}} \sum_{t} \sum_{i} \log P(X_i = x_i^{(t)} \mid \mathrm{Parents}(X_i) = \mathrm{Parents}(x_i), \boldsymbol{\theta})
\end{aligned}
$$

If the parameters **θ** are partitioned by CPT …

$$
= \arg\max_{\boldsymbol{\theta}} \sum_{i} \sum_{t} \log P(X_i = x_i^{(t)} \mid \mathrm{Parents}(X_i) = \mathrm{Parents}(x_i), \boldsymbol{\theta}_i)
$$

Key Idea

- For known structure and fully observed data, MLE for a Bayesian network whose CPDs have disjoint parameters

equates to

MLE for each of its CPDs.

Bad News for Markov Networks

- The global normalization constant (Z) kills decomposability.

$$
\begin{aligned}
\boldsymbol{\theta}_{\mathrm{MLE}} &= \arg\max_{\boldsymbol{\theta}} \prod_t P(\boldsymbol{X} = \boldsymbol{x}^{(t)} \mid \boldsymbol{\theta}) \\
&= \arg\max_{\boldsymbol{\theta}} \prod_t \frac{1}{Z} \prod_i \phi_i(\boldsymbol{x}_i^{(t)}) \\
&= \arg\max_{\boldsymbol{\theta}} \left(\sum_t \sum_i \log \phi_i(\boldsymbol{x}_i^{(t)}) \right) - T \log Z
\end{aligned}
$$

- Solving for the parameters becomes more complicated.

Example Task: Entity Recognition

- "The outcome will help determine whether Mr. Boehner is leading his party or following the demands of the Tea Party."

What are the Parameters?

- How do the factors ϕ get expressed as parameters $\boldsymbol{\theta}$?
- Often, we adopt a log-linear parameterization.
- We covered this in lecture 9.

Log-Linear Markov Networks

- A **feature** is a function f : Val($\mathbf{D}_i$) → $\mathbb{R}$.
- Log-linear model:

$$
\begin{aligned}
P(\boldsymbol{X}) &= \frac{1}{Z} e^{\sum_i \log \phi_i(\boldsymbol{D}_i)} \\
&= \frac{1}{Z} e^{-\sum_i \psi_i(\boldsymbol{D}_i)} \\
&= \frac{1}{Z} e^{\sum_i \sum_j f_j(\boldsymbol{D}_i) w_j}
\end{aligned}
$$

- Features and weights can be *reused* for different factors.
  - Typical: features designed by expert, weights learned from data.
  - Note that this breaks parameter independence.

Log-Linear Markov Networks

- A **feature** is a function f : Val($\mathbf{D}_i$) → $\mathbb{R}$.
- Log-linear model:

$$\begin{aligned} P(\boldsymbol{X}) &= \frac{1}{Z} e^{\sum_i \log \phi_i(\boldsymbol{D}_i)} \\ &= \frac{1}{Z} e^{-\sum_i \psi_i(\boldsymbol{D}_i)} \\ &= \frac{1}{Z} e^{\sum_i \sum_j f_j(\boldsymbol{D}_i) w_j} \end{aligned}$$

- Log of the probability is *linear* in the weights **w**.
  - Ignoring Z, which is a constant for a given **w**.

Log-Likelihood Function for Log-Linear Models

$$\begin{aligned}\boldsymbol{\theta}_{\mathrm{MLE}} &= \arg\max_{\boldsymbol{\theta}} \left(\sum_t \sum_i \log \phi_i(\boldsymbol{x}_i^{(t)}) \right) - T \log Z \\ &= \arg\max_{\mathbf{w}} \left(\sum_t \sum_i \sum_j w_j f_j(\boldsymbol{x}_i^{(t)}) \right) - T \log Z\end{aligned}$$

- The first term is linear in **w**.
- The second term is also a function of **w**:

$$\log Z = \log \sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \exp \left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i) \right)$$

Log-Likelihood Function for Log-Linear Models

- log Z does not decompose.
  - No closed form solution.
  - Even *computing* the likelihood requires inference!
- It is, however, *concave*.
- The weights **w** are *unconstrained*.

$$\log Z = \log \sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \exp \left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i) \right)$$

Optimization Returns

- We talked about two abstract optimization problems last time:
  - Integer linear programming (NP hard)
  - Linear programming (solvable in poly time)

- **Convex** optimization: globally concave or globally convex function
- **Unconstrained** optimization: $\mathbf{w} \in \mathbb{R}^d$

Solving Unconstrained Convex Optimization Problems

- Gradient descent and variations
  - Stochastic gradient descent
  - Coordinate descent
  - Conjugate gradient descent
  - Newton, Quasi-Newton methods
- Specialized algorithms
  - For Markov networks, iterative proportional fitting, a.k.a. iterative scaling.

The Gradient of Log-Likelihood

$$\frac{\partial}{\partial w_k}\left[\left(\sum_t\sum_i\sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T\log Z\right]$$

$$= \frac{\partial}{\partial w_k}\left[\left(\sum_t\sum_i\sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T\log\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right]$$

$$= \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - T\frac{\partial}{\partial w_k}\left[\log\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right]$$

$$= \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - T\frac{\frac{\partial}{\partial w_k}\left[\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right]}{Z}$$

$$= \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z}\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\frac{\partial}{\partial w_k}\left[\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right]$$

$$= \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z}\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\left(\sum_i f_k(\boldsymbol{x}_i)\right)$$

$$= T\left(\frac{\sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)})}{T} - \sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\frac{\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)}{Z}\left(\sum_i f_k(\boldsymbol{x}_i)\right)\right)$$

$$= T\left(\mathbb{E}_{\tilde{P}}\left[\sum_i f_k(\boldsymbol{x}_i)\right] - \mathbb{E}_{P_{\mathbf{w}}}\left[\sum_i f_k(\boldsymbol{x}_i)\right]\right)$$

Flesh out Z.

The Gradient of Log-Likelihood

$$
\begin{aligned}
& \frac{\partial}{\partial w_k}\left[\left(\sum_t\sum_i\sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T\log Z\right] \\
= & \frac{\partial}{\partial w_k}\left[\left(\sum_t\sum_i\sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T\log\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - T\frac{\partial}{\partial w_k}\left[\log\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - T\frac{\frac{\partial}{\partial w_k}\left[\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right]}{Z} \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z}\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\frac{\partial}{\partial w_k}\left[\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z}\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\left(\sum_i f_k(\boldsymbol{x}_i)\right) \\
= & T\left(\frac{\sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)})}{T} - \sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\frac{\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)}{Z}\left(\sum_i f_k(\boldsymbol{x}_i)\right)\right) \\
= & T\left(\mathbb{E}_{\tilde{P}}\left[\sum_i f_k(\boldsymbol{x}_i)\right] - \mathbb{E}_{P_{\mathbf{w}}}\left[\sum_i f_k(\boldsymbol{x}_i)\right]\right)
\end{aligned}
$$

Linear function is easy.

T is constant with respect to **w**.

The Gradient of Log-Likelihood

$$
\begin{aligned}
& \frac{\partial}{\partial w_k}\left[\left(\sum_t \sum_i \sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T \log Z\right] \\
= & \frac{\partial}{\partial w_k}\left[\left(\sum_t \sum_i \sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T \log \sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \exp\left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t \sum_i f_k(\boldsymbol{x}_i^{(t)}) - T \frac{\partial}{\partial w_k}\left[\log \sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \exp\left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t \sum_i f_k(\boldsymbol{x}_i^{(t)}) - T \frac{\frac{\partial}{\partial w_k}\left[\sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \exp\left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i)\right)\right]}{Z}
\end{aligned}
$$

$$
\begin{aligned}
= & \sum_t \sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z} \sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \frac{\partial}{\partial w_k}\left[\exp\left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t \sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z} \sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \exp\left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i)\right)\left(\sum_i f_k(\boldsymbol{x}_i)\right) \\
= & T\left(\frac{\sum_t \sum_i f_k(\boldsymbol{x}_i^{(t)})}{T} - \sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \frac{\exp\left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i)\right)}{Z}\left(\sum_i f_k(\boldsymbol{x}_i)\right)\right) \\
= & T\left(\mathbb{E}_{\tilde{P}}\left[\sum_i f_k(\boldsymbol{x}_i)\right] - \mathbb{E}_{P_{\mathbf{w}}}\left[\sum_i f_k(\boldsymbol{x}_i)\right]\right)
\end{aligned}
$$

Logarithm rule for derivatives.

Use “Z” shorthand.

The Gradient of Log-Likelihood

$$
\begin{aligned}
& \frac{\partial}{\partial w_k}\left[\left(\sum_t\sum_i\sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T\log Z\right] \\
= & \frac{\partial}{\partial w_k}\left[\left(\sum_t\sum_i\sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T\log\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - T\frac{\partial}{\partial w_k}\left[\log\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - T\frac{\frac{\partial}{\partial w_k}\left[\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right]}{Z} \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z}\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\frac{\partial}{\partial w_k}\left[\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right]
\end{aligned}
$$

$$
\begin{aligned}
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z}\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\left(\sum_i f_k(\boldsymbol{x}_i)\right) \\
= & T\left(\frac{\sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)})}{T} - \sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\frac{\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)}{Z}\left(\sum_i f_k(\boldsymbol{x}_i)\right)\right) \\
= & T\left(\mathbb{E}_{\tilde{P}}\left[\sum_i f_k(\boldsymbol{x}_i)\right] - \mathbb{E}_{P_{\mathbf{w}}}\left[\sum_i f_k(\boldsymbol{x}_i)\right]\right)
\end{aligned}
$$

Use the sum rule.

The Gradient of Log-Likelihood

$$
\begin{aligned}
& \frac{\partial}{\partial w_k}\left[\left(\sum_t \sum_i \sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T \log Z\right] \\
= & \frac{\partial}{\partial w_k}\left[\left(\sum_t \sum_i \sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T \log \sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \exp\left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t \sum_i f_k(\boldsymbol{x}_i^{(t)}) - T \frac{\partial}{\partial w_k}\left[\log \sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \exp\left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t \sum_i f_k(\boldsymbol{x}_i^{(t)}) - T \frac{\frac{\partial}{\partial w_k}\left[\sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \exp\left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i)\right)\right]}{Z} \\
= & \sum_t \sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z} \sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \frac{\partial}{\partial w_k}\left[\exp\left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t \sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z} \sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \exp\left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i)\right)\left(\sum_i f_k(\boldsymbol{x}_i)\right) \\
= & T\left(\frac{\sum_t \sum_i f_k(\boldsymbol{x}_i^{(t)})}{T} - \sum_{\boldsymbol{x} \in \mathrm{Val}(\boldsymbol{X})} \frac{\exp\left(\sum_i \sum_j w_j f_j(\boldsymbol{x}_i)\right)}{Z}\left(\sum_i f_k(\boldsymbol{x}_i)\right)\right) \\
= & T\left(\mathbb{E}_{\tilde{P}}\left[\sum_i f_k(\boldsymbol{x}_i)\right] - \mathbb{E}_{P_{\mathbf{w}}}\left[\sum_i f_k(\boldsymbol{x}_i)\right]\right)
\end{aligned}
$$

Exponential rule.

The Gradient of Log-Likelihood

$$
\begin{aligned}
& \frac{\partial}{\partial w_k}\left[\left(\sum_t\sum_i\sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T\log Z\right] \\
= & \frac{\partial}{\partial w_k}\left[\left(\sum_t\sum_i\sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T\log\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - T\frac{\partial}{\partial w_k}\left[\log\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - T\frac{\frac{\partial}{\partial w_k}\left[\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right]}{Z} \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z}\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\frac{\partial}{\partial w_k}\left[\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z}\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\left(\sum_i f_k(\boldsymbol{x}_i)\right) \\
= & T\left(\frac{\sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)})}{T} - \sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\frac{\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)}{Z}\left(\sum_i f_k(\boldsymbol{x}_i)\right)\right) \\
= & T\left(\mathbb{E}_{\tilde{P}}\left[\sum_i f_k(\boldsymbol{x}_i)\right] - \mathbb{E}_{P_{\mathbf{w}}}\left[\sum_i f_k(\boldsymbol{x}_i)\right]\right)
\end{aligned}
$$

Rearrange terms.

The Gradient of Log-Likelihood

$$
\begin{aligned}
& \frac{\partial}{\partial w_k}\left[\left(\sum_t\sum_i\sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T\log Z\right] \\
= & \frac{\partial}{\partial w_k}\left[\left(\sum_t\sum_i\sum_j w_j f_j(\boldsymbol{x}_i^{(t)})\right) - T\log\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - T\frac{\partial}{\partial w_k}\left[\log\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - T\frac{\frac{\partial}{\partial w_k}\left[\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right]}{Z} \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z}\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\frac{\partial}{\partial w_k}\left[\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\right] \\
= & \sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)}) - \frac{T}{Z}\sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)\left(\sum_i f_k(\boldsymbol{x}_i)\right) \\
= & T\left(\frac{\sum_t\sum_i f_k(\boldsymbol{x}_i^{(t)})}{T} - \sum_{\boldsymbol{x}\in\mathrm{Val}(\boldsymbol{X})}\frac{\exp\left(\sum_i\sum_j w_j f_j(\boldsymbol{x}_i)\right)}{Z}\left(\sum_i f_k(\boldsymbol{x}_i)\right)\right) \\
= & T\left(\mathbb{E}_{\tilde{P}}\left[\sum_i f_k(\boldsymbol{x}_i)\right] - \mathbb{E}_{P_{\mathbf{w}}}\left[\sum_i f_k(\boldsymbol{x}_i)\right]\right)
\end{aligned}
$$

Difference of expectations!

The Gradient of Log-Likelihood

- Difference of expectations!

$$T\left(\mathbb{E}_{\tilde{P}}\left[\sum_i f_k(\boldsymbol{x}_i)\right] - \mathbb{E}_{P_{\mathbf{w}}}\left[\sum_i f_k(\boldsymbol{x}_i)\right]\right)$$

- At a maximum of the likelihood function
- This form helps us prove the global concavity of the log-likelihood function.
  - Second derivative matrix (Hessian) is a correlation matrix of the features; it is positive semidefinite.
- The first term is simple; what about the second?

Feature Expectations

$$\mathbb{E}_{P_{\mathbf{w}}}\left[\sum_i f_k(\boldsymbol{x}_i)\right] \quad = \quad \sum_i \mathbb{E}_{P_{\mathbf{w}}}[f_k(\boldsymbol{x}_i)] \quad = \quad \sum_i \sum_{\boldsymbol{c}\in \mathrm{Val}(\boldsymbol{X}_i)} P_{\boldsymbol{w}}(\boldsymbol{X}_i = \boldsymbol{c}) f_k(\boldsymbol{c})$$

- Linearity of expectation.
- Feature expectations are easily obtained from *marginals*.
  - We spent seven lectures on that problem!

Bayesian Learning

Maximum likelihood estimation: $\max_{\boldsymbol{\theta}} P(\boldsymbol{X} \mid \boldsymbol{\theta})$

Bayes' rule:

$$\begin{aligned}
\max_{\boldsymbol{\theta}} P(\boldsymbol{\theta} \mid \boldsymbol{X}) &= \max_{\boldsymbol{\theta}} \frac{P(\boldsymbol{X} \mid \boldsymbol{\theta}) P(\boldsymbol{\theta})}{P(\boldsymbol{X})} \\
&= \max_{\boldsymbol{\theta}} \frac{P(\boldsymbol{X} \mid \boldsymbol{\theta}) P(\boldsymbol{\theta})}{\int P(\boldsymbol{X} \mid \boldsymbol{\theta}) P(\boldsymbol{\theta}) \, d\boldsymbol{\theta}} \\
&= \max_{\boldsymbol{\theta}} P(\boldsymbol{X} \mid \boldsymbol{\theta}) P(\boldsymbol{\theta})
\end{aligned}$$

In Log Space

MLE

- $\max_{\boldsymbol{\theta}} \Sigma_t \log P(\mathbf{X}^{(t)} \mid \boldsymbol{\theta})$
- "Make the data likely."

- Closed form or convex in many cases.

Bayesian

- $\max_{\boldsymbol{\theta}} \Sigma_t \log P(\mathbf{X}^{(t)} \mid \boldsymbol{\theta}) + \log P(\boldsymbol{\theta})$
- "Make the data likely … and make the model likely, too."

- Closed form or convex in many cases.

Lecture 6

Priors for Log-Linear Parameters

- For Bayesian networks, we fixated on conjugacy.
  - Conjugate priors for log-linear parameters don't decompose as nicely as the Dirichlet. See K&F 20.4.2.

- Not here; we already have to solve an optimization problem, so we're pretty open to any prior where log P(**w**) is concave.

Gaussian Prior on **w**

- Let each w_j have a prior that says its mean is 0 and its variance is σ^2.

$$\begin{aligned}
\log P(\mathbf{w}) &= \sum_j \log\left(\frac{1}{\sqrt{2\pi\sigma^2}}\exp\left(-\frac{w_j^2}{2\sigma^2}\right)\right) \\
&= -\sum_j \frac{w_j^2}{2\sigma^2} + \text{constant} \\
&= -\frac{1}{2\sigma^2}\|\mathbf{w}\|_2^2
\end{aligned}$$

- Result: quadratic/Euclidean/L_2 penalty on likelihood.
- Generalizes **ridge regression**.

Laplacian Prior on **w**

- Let each w_j have a Laplacian prior with parameter β.

$$\begin{aligned}\log P(\mathbf{w}) &= \sum_j \log\left(\frac{1}{2\beta}\exp\left(-\frac{|w_j|}{\beta}\right)\right)\\ &= -\frac{|w_j|}{\beta} + \text{constant}\\ &= -\frac{1}{\beta}\|\mathbf{w}\|_1\end{aligned}$$

- Result: absolute value/L_1 penalty on likelihood.
  - Still concave, but not everywhere differentiable.
- Generalizes **lasso regression**.

Priors for Log-Linear Parameters

- Both the Gaussian and the Laplacian priors push the weights toward zero.
  - Laplacian pushes "harder" near zero, resulting in many weights being zero at the optimum ("**sparsity**").
- Weights near zero make the distribution over **X** flatter (smoother).
- Choice of the hyperparameters (σ^2 or β) can have a big effect.
  - Cross-validation.

Discriminative Learning

Goal of Learning?

- **Density estimation**: return a model M that precisely captures P*
- **Knowledge discovery**: reveal facts about the domain.
- **Prediction**: optimize quality of answers to specific queries

Generative vs. Discriminative

- Every model we've looked at so far this semester is generative, defining a distribution P(**X**).
- Often we are less interested in density estimation than accurate performance on some query: P(**Y** | **X**).
- Discriminative models seek to perform well on a particular query.

Understanding Conditional Random Fields

- We know that graphical models can be used to define conditional distributions rather than joint ones.
  - This is not quite the same as having a joint distribution and conditioning on evidence.
  - The model really has nothing to say about P(**X**), only P (**Y** | **X**).
- Intuitive motivation: don't waste your time learning the density of something that will always be in evidence.

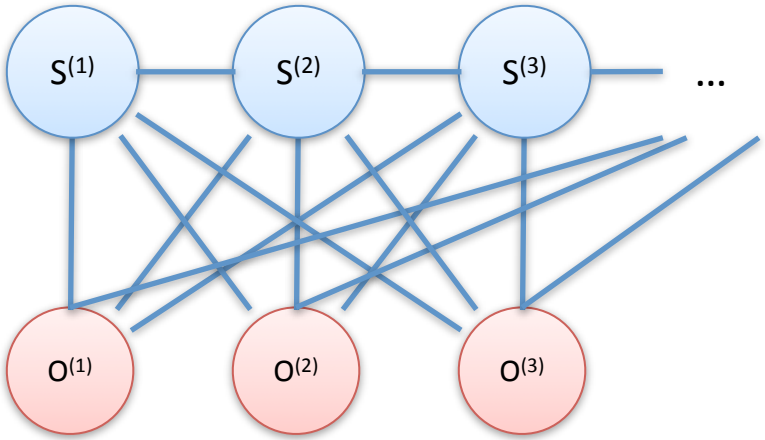
Conditional Random Fields

- Normalization now depends on **X**. Because **X** is always observed, every factor can depend on any part of **X**.

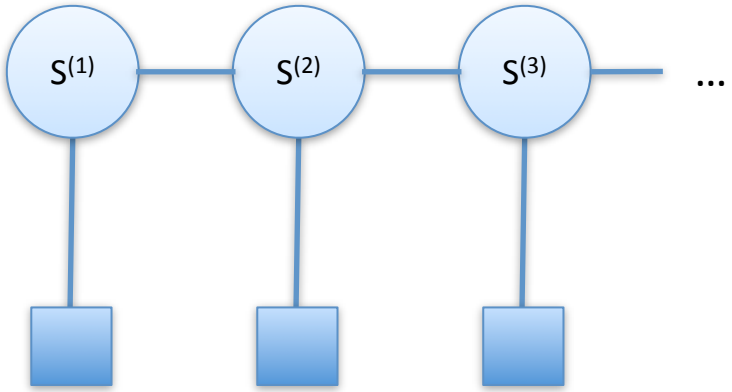
$$P(\boldsymbol{Y} \mid \boldsymbol{X}) = \frac{1}{Z(\boldsymbol{X})} \prod_i \phi_i(\boldsymbol{Y}_i, \boldsymbol{X})$$

$$Z(\boldsymbol{X}) = \sum_{\boldsymbol{y} \in \mathrm{Val}(\boldsymbol{Y})} \prod_i \phi_i(\boldsymbol{y}_i, \boldsymbol{X})$$

Example



Example



Conditional Random Fields

- Normalization now depends on **X**. Because **X** is always observed, every factor can depend on any part of **X**.

$$P(\boldsymbol{Y} \mid \boldsymbol{X}) = \frac{1}{Z(\boldsymbol{X})} \prod_i \phi_i(\boldsymbol{Y}_i, \boldsymbol{X})$$

$$Z(\boldsymbol{X}) = \sum_{\boldsymbol{y} \in \mathrm{Val}(\boldsymbol{Y})} \prod_i \phi_i(\boldsymbol{y}_i, \boldsymbol{X})$$

- Log-linear form:

$$\phi_i(\boldsymbol{Y}_i, \boldsymbol{X}) = \exp \mathbf{w}^\top \mathbf{f}(\boldsymbol{Y}_i, \boldsymbol{X})$$

Maximizing Conditional Likelihood

$$\begin{aligned}
\boldsymbol{\theta}_{\text{MLE}} &= \arg\max_{\boldsymbol{\theta}} \prod_t P(\boldsymbol{y}^{(t)} \mid \boldsymbol{x}^{(t)}, \boldsymbol{\theta}) \\
&= \arg\max_{\boldsymbol{\theta}} \sum_t \log P(\boldsymbol{y}^{(t)} \mid \boldsymbol{x}^{(t)}, \boldsymbol{\theta}) \\
\mathbf{w}_{\text{MLE}} &= \arg\max_{\mathbf{w}} \sum_t \left(\sum_i \mathbf{w}^\top \mathbf{f}(\boldsymbol{y}_i^{(t)}, \boldsymbol{x}_i^{(t)}) - \log Z_{\mathbf{w}}(\boldsymbol{x}_i^{(t)}) \right)
\end{aligned}$$

Compare to MLE for the classic Markov network:

$$\mathbf{w}_{\text{MLE}} = \arg\max_{\mathbf{w}} \sum_t \left(\sum_i \mathbf{w}^\top \mathbf{f}(\boldsymbol{y}_i^{(t)}, \boldsymbol{x}_i^{(t)}) - \log Z_{\mathbf{w}} \right)$$

Training the CRF

- Everything is the same as doing MLE in classic Markov networks, except now we have T different log partition functions.
  - Each requires marginalizing over **Y** for a single **x**, rather than over all random variables.
- CRF likelihood first derivatives:

$$\sum_t \left(\sum_i \mathbf{f}(\boldsymbol{y}_i^{(t)}, \boldsymbol{x}^{(t)}) - \mathbb{E}_{P_{\mathbf{w}}}[\mathbf{f}(\boldsymbol{Y}_i, \boldsymbol{x}^{(t)})] \right)$$

Additional Notes: CRF

- CRFs appear to be *way* more widely used than classic Markov networks.
  - The **x**-specific partition functions are much less painful.
- Same training methods apply as before.
  - Same advice: L-BFGS, stochastic gradient descent.
  - Same priors: Gaussian, Laplacian

My Advice on Maximizing Likelihood

- If inference is relatively fast (on the whole dataset): use a **quasi-Newton** method like limited memory BFGS (L-BFGS).
  - "Batch" algorithm.
- If inference is relatively slow or you have massive amounts of training data, use **stochastic gradient descent**.
  - "Online" algorithm.
  - Lets you avoid Z, because you only need to calculate the additive updates.

CRF Pseudocode: Value and Gradient

- for t = {1, …, T} *// for each training example*
- likelihood += log_score($y^{(t)}$)
- (marginals,logz) = inference ($x^{(t)}$)
- likelihood -= logz
- for i, y_i, j *// for each clique, assignment, feature*
- gradient(j) -= marginals(i,y_i) * $f_j(x^{(t)}, y_i)$
- gradient += constraints *// constraints cached*
- likelihood += prior(w)
- gradient += prior_gradient(w)

More implementation advice

- Cod structure: Optimizer asks for the likelihood and gradient at with parameters
- Efficiency:
  - Cache “constraints” (data expectations)
  - Cache features
  - Parallelize inference step
  - Online learning with stochastic gradient
- Gaussian prior typical values: 1, 10
